Executive Summary

Combined heat and power (CHP) is an efficient and clean approach to generating electric power and useful thermal energy from a single fuel source. Instead of purchasing electricity from the distribution grid and separately burning fuel in an on-site furnace or boiler to produce thermal energy, an industrial or commercial facility can use combined heat and power to provide both services in one, energy-efficient step. CHP is a clean energy solution that directly addresses a number of national priorities, including improving U.S. competitiveness by:

- reducing energy operating costs,
- increasing energy efficiency,
- reducing greenhouse gas emissions,
- enhancing our energy infrastructure,
- improving energy security and resiliency, and
- “growing” the U.S. economy.

There are several emerging market drivers contributing to current CHP growth, including lower energy operating costs, CHP-friendly environmental regulations, resiliency initiatives, federal and state policies and incentives, utility support, and project replicability. The drivers that are currently influencing the market growth of CHP are part of a larger recognition of the benefits that CHP provides both to the user and the nation as a whole. CHP can reduce strain on the electric grid and lower greenhouse gas (GHG) and other harmful emissions. CHP can lessen the need for new transmission and distribution infrastructure and uses abundant clean domestic energy sources such as natural gas and biomass.

CHP can be utilized in a variety of industrial facilities and commercial buildings with coincident power and thermal loads. Industrial manufacturing facilities that are a good fit for CHP include food processing, chemicals, refining and metal manufacturing. For commercial buildings, year-round coincident on-site loads suitable for CHP are present at hospitals, multifamily buildings, colleges and universities, waste water treatment plants¹ and military campuses. In addition to industrial and commercial facilities, CHP can also be integrated into district energy systems.

This study considers both traditional “topping cycle” CHP and “bottoming cycle” or waste heat to power CHP (WHP CHP). Topping cycle CHP systems are the most common CHP systems currently in use. In a topping cycle system, fuel is first combusted to generate electricity. A portion of the heat left over from the electricity generation process is then converted into useful thermal energy (e.g. heating, hot water, or steam for industrial processes). A bottoming-cycle CHP system, which will be referred to as WHP CHP in this report, uses the reverse process. Fuel is first combusted to provide thermal input to industrial process equipment like a kiln or furnace, and the heat rejected from the process is then captured and used for power production.

¹ In this report, waste water treatment plants refer to facilities that treat water, wastewater and sewage/sanitary waste.

The study discusses the typical industrial facilities and commercial buildings that support “topping cycle” CHP, “bottoming cycle” or waste heat to power CHP (WHP CHP), and district energy CHP. The goal of the report is to provide data on the technical potential for CHP in sufficient detail for stakeholders to consider combined heat and power in strategic energy planning and energy efficiency program design. Data are provided nationally by CHP system size range, facility type, and location. Each state’s technical potential is also delineated by these characteristics.

The technical potential is an estimation of market size constrained only by technological limits — the ability of CHP technologies to fit customer energy needs without regard to economic or market factors. Across all CHP categories, there is estimated to be more than 240GW of technical potential at over 291,000 sites within the U.S. **Table 1** represents the total CHP technical potential identified in the United States by application or business type, including on-site CHP at industrial and commercial facilities, export, waste heat to power applications or district energy systems that could integrate CHP.

Table 1: Total U.S. CHP Technical Potential Across All Facility Types

Business Type	50-500kW		0.5 - 1 MW		1-5 MW		5-20 MW		>20 MW		Total Sites	Total Capacity (MW)
	# Sites	Capacity (MW)	# Sites	Capacity (MW)	# Sites	Capacity (MW)	# Sites	Capacity (MW)	# Sites	Capacity (MW)

U.S. DOE CHP Deployment Program, 2016.

In contrast to the existing facilities with installed CHP, which are heavily concentrated at large industrial manufacturing facilities, a significant portion of the remaining technical potential for on-site CHP in the U.S. is located in commercial facilities. **Figure 1** shows both existing CHP and estimated technical potential capacity for on-site CHP in the most predominant sectors.

Figure 1: Existing CHP Compared to On-Site Technical Potential by Sector²

U.S. DOE CHP Deployment Program, 2016.

The technical potential for CHP is concentrated in states with large population centers (leading to a large amount of commercial facilities) and/or a strong industrial presence. **Table 2** displays the total CHP technical potential in the U.S. on a state-by-state basis. On-site CHP potential includes industrial, commercial, and waste heat to power at the host facility. Export potential includes all electricity in excess of what can be used by the host facility and that could be sold to the electric grid, including district energy with CHP potential.

² More detailed information for all industrial and commercial sectors is presented in Section III.

I. Introduction

Combined heat and power (CHP) is an efficient and clean approach to generating electric power and useful thermal energy from a single fuel source. Instead of purchasing electricity from the distribution grid and separately burning fuel in an on-site furnace or boiler to produce thermal energy, an industrial or commercial facility can use combined heat and power to provide both services in one energy-efficient step. The average efficiency of power generation in the United States has only improved by three percentage points since the 1960s, from 33% to 36% today.³ CHP systems capture this waste energy and use it to meet thermal needs, such as providing process heat, heating and/or cooling to factories and businesses, saving money and reducing emissions. CHP is a commercially-available, clean energy solution that directly addresses a number of national priorities including improving the competitiveness of U.S. manufacturing through reduced costs, increasing energy efficiency, reducing emissions, enhancing our energy infrastructure, improving energy security and resiliency, and growing our economy.

While CHP has been in use in the United States for more than 100 years, it remains an underutilized resource today. CHP currently represents approximately 8% of U.S. generating capacity⁴, compared to over 30% in countries such as Denmark, Finland and the Netherlands. Its use in the U.S. has been limited, particularly in recent years, by a host of market and non-market barriers. Nevertheless, the outlook for increased CHP use is bright as policymakers at the federal and state level are recognizing the potential benefits and the role that this technology could play in providing clean, reliable, cost-effective energy services to industry and businesses.

There are several emerging market drivers contributing to current combined heat and power growth, including:

- *Lower Operating Costs:* Compared to conventional power generation techniques, CHP systems can save money through increased energy efficiency. Higher operating efficiencies enable CHP systems to consume up to 40% less fuel while generating the same amount of power and useful thermal energy as separate heat and power systems. With stable and low-cost natural gas supply forecasts stemming from the development of shale gas production, the economics of CHP have been improving.⁵
- *Environmental Regulations:* Recent environmental regulations have created opportunities for combined heat and power to help meet compliance goals.
 - *EPA Clean Power Plan.*⁶ The Clean Power Plan (CPP) establishes state-specific targets for reducing carbon emissions from existing power plants. The plan allows

³ U.S. Energy Information Administration, Form EIA-923, Form EIA-906, Form EIA-920, and Form EIA-860.

⁴ U.S. Energy Information Administration, Form EIA-860, 'Annual Electric Generator Report.' Shows a net winter electric generating capacity of 1,100,772 MW.

⁵ Backer, Scott, "CHP Gains Traction as an Economic Energy Solution," *Cogeneration and On-site Power Production* (Jan 2012), accessed December 2014. <http://www.cospp.com/articles/print/volume-13/issue-4/features/chp-gains-traction-as-an-economic-energy-solution.html>

⁶ For more information on the Clean Power Plan, please see the EPA's CPP website at <http://www.epa.gov/cleanpowerplan/clean-power-plan-existing-power-plants>

states to use CHP under the broader aegis of energy efficiency measures as a means to comply.

- *Boiler MACT*.⁷ The national emissions standard for hazardous air pollutants (known as the Boiler MACT rule) requires affected industrial and commercial boilers to meet new emissions limits. Converting existing boilers to natural gas CHP can help facilities to achieve compliance.
- *Resiliency*: In the event of a man-made or natural disaster that causes a grid outage, CHP systems can be configured to be more resilient and reliable than traditional backup generators. During recent storm events such as Hurricane Sandy, CHP systems enabled a number of critical infrastructure facilities to continue their operations when the electric grid went down. The U.S. Department of Energy and Environmental Protection Agency have provided guidance on how CHP can enhance the resiliency of critical facilities, and the best way to size such systems.⁸ The U.S. DOE is launching a new CHP for Resiliency Accelerator early in 2016 to collaborate with states, cities, and utilities to incorporate CHP in resiliency planning efforts.
- *Policy Support*: A number of federal and state policies and financial incentives have encouraged the market for combined heat and power. At the federal level, currently there is a 10% investment tax credit for CHP. In August of 2012, the White House released an executive order⁹ creating a goal of adding 40 GW of new CHP capacity. At the state level, several state climate and energy plans include CHP as a way to meet clean energy goals.¹⁰
- *Utility Interest*: Due to increasing customer awareness of distributed generation generally, utility interest in combined heat and power, a form of distributed generation, has increased. Many utilities are proactively engaging with new stakeholders and finding ways to incorporate CHP into energy efficiency programs and plans for new generation. For example, the Baltimore Gas and Electric (BG&E) Smart Energy Savers Program

Utility Incentives

The Baltimore Gas and Electric (BG&E) Smart Energy Savers Program provides incentives up to \$2.5 million to industrial and commercial customers who install an on-site CHP system. The program includes both capital and production incentives based on the progress of the project. Capacity incentives are available for system design and installation and the production incentive is available for the first 18 months of service.

⁷ For more information on the Boiler MACT regulation, please see the EPA's Boiler MACT website at <http://www3.epa.gov/airquality/combustion/actions.html>.

⁸ http://www1.eere.energy.gov/manufacturing/distributedenergy/pdfs/chp_for_reliability_guidance.pdf

⁹ <https://www.whitehouse.gov/the-press-office/2012/08/30/executive-order-accelerating-investment-industrial-energy-efficiency>

¹⁰ For more information on state-level energy policies and initiatives, please see the Database of State Incentives for Renewables and Efficiency at www.dsireusa.org.

provides incentives up to \$2.5 million to industrial and commercial customers who install on an on-site CHP system. The program includes both capital and production incentives based on the progress of the project. Capacity incentives are available for system design and installation and the production incentive is available for the first 18 months of service.¹¹ Southern California Gas and Jacksonville Energy Authority are also both working towards owning and operating CHP systems at customer sites.

- *Project Replicability.* Advancements in the packaging of CHP equipment have led to the emergence of a growing number of packaged CHP system options that are available at a variety of system sizes. These systems allow for streamlined installation and maintenance and are increasingly being used by national organizations with multiple facilities as a way to install standardized CHP systems at their facilities. The U.S. DOE anticipates launching a Packaged CHP System Challenge in the summer of 2016, aimed at capitalizing on the replicability, risk reduction, and installation process simplification that is associated with these systems.

CHP can:

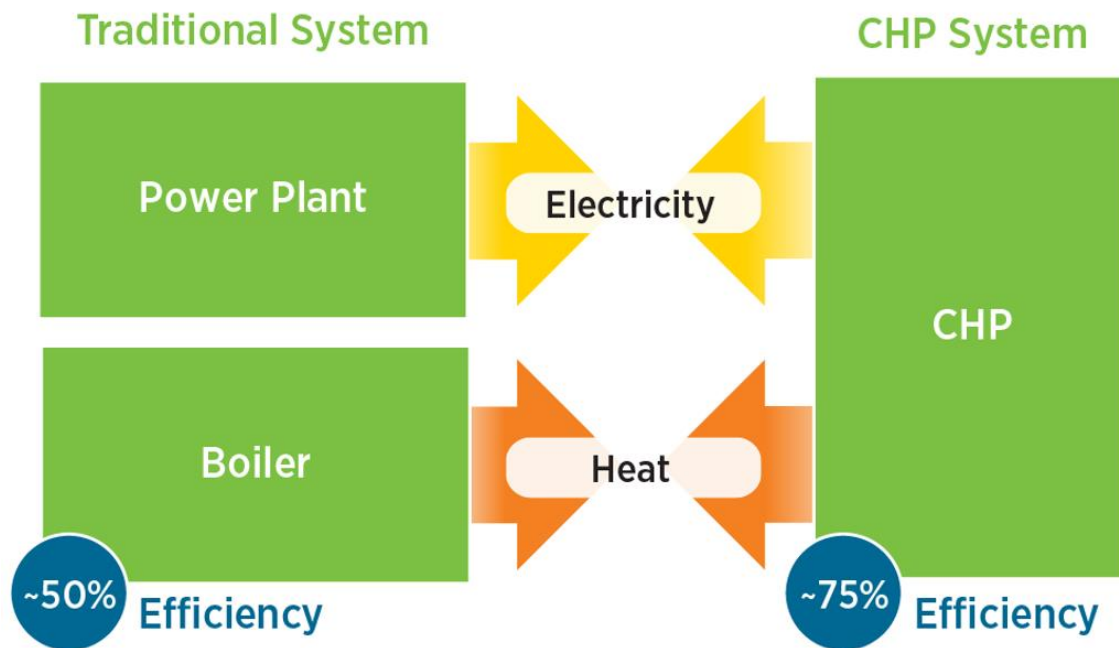

- Increase energy efficiency
- Reduce air pollutant emissions
- Reduce site energy costs
- Enhance site energy reliability
- Delay need for new T&D infrastructure
- Use clean domestic energy sources (natural gas, biomass, and biogas)

The current drivers influencing the market growth of CHP are part of a larger recognition of the benefits that CHP provides both to the user and the nation. These benefits to the individual owner translate to the national level as well. Combined heat and power reduces strain on the electric grid and reduces greenhouse gas (GHG) and other harmful emissions. CHP also lessens the need for new transmission and distribution infrastructure as on-site generation does not need to be transported from a central generation plant. Typically CHP uses abundant clean, domestic energy sources such as natural gas and biomass. These benefits improve U.S. manufacturing competitiveness and make use of highly skilled American labor and American technology.¹²

Figure I-1 illustrates the efficiency benefits that a typical CHP system achieves by offsetting the need for grid electricity and for steam or hot water that would otherwise be produced from an on-site boiler. When electricity and thermal energy are provided separately, overall energy efficiency ranges from 45 – 55%. While efficiencies vary for CHP installations based on site-specific parameters, a properly designed CHP system will typically operate with an overall efficiency of 65 – 85%.

Figure I-1: Energy Efficiency Advantage of CHP Compared to Traditional Energy Supply

U.S. DOE CHP Deployment Program, 2016.

Though there are many environmental and economic benefits to combined heat and power, there are also barriers to CHP deployment as well. These barriers include:

- Unclear Utility Value Proposition:** Many investor-owned electric utilities still view customer-sited CHP as a source of revenue erosion due to traditional business models and regulations linking cost recovery and utility revenue to electricity sales. Most facilities that install CHP remain connected to the grid and need to rely on their servicing utility for supplemental power needs beyond their self-generation capacity, as well as for standby and back-up service during outages or planned maintenance. As a result, the policies and actions of utilities can make or break a CHP project's economics. Utility tariff structures and standby rates impact the economics of on-site generation. However, there are several options that utilities can provide to help minimize the costs that customer-generators impose on the electric system. These include allowing the customer to provide their utility with a load reduction plan, offering a self-supply option for reserves, offering daily or monthly as-used demand charges, scheduling maintenance at off-peak times, and allowing customer-generators to buy all of their backup power at market price.¹³
- Market and Non-Market Uncertainties:** CHP requires a significant capital investment and the equipment has a long life – potentially over 20 years. It can be challenging to make

¹³ State and Local Energy Efficiency Action Network, *Guide to the Successful Implementation of State Combined Heat and Power Policies*, pp 8-9, 2013.

https://www4.eere.energy.gov/seeaction/system/files/documents/see_action_chp_policies_guide.pdf

investment decisions in a rapidly changing policy and economic environment. Uncertainties affecting project economics include: fuel and electricity prices, regional/national economic conditions, market sector growth, utility and power market regulation, and environmental policy.

- *End-User Awareness and Economic Decision-Making:* CHP is not regarded as part of most end-users' core business focus and, as such, is sometimes subject to higher investment hurdle rates than competing internal options. In addition, many potential project hosts are not fully aware of the full array of benefits, or are overly sensitive to perceived CHP investment risks.
- *Local Permitting and Siting Issues:* CHP installations must comply with a host of local zoning, environmental, health and safety requirements at the site. These include rules on air and water quality, fire prevention, fuel storage, hazardous waste disposal, worker safety and building construction standards. Navigating these rules requires interaction with various local agencies including fire districts, air districts, and water districts and planning commissions, many of which may have no previous experience with a CHP project and are unfamiliar with the technologies and systems.

To help mitigate the impacts of these barriers, the U.S. DOE has established seven regional CHP Technical Assistance Partnerships (CHP TAPs) to help promote and assist in transforming the market for CHP, waste heat to power CHP, district energy, and microgrids with CHP. Key services provided by the CHP TAPs are market opportunity analysis, education and outreach, and technical assistance.¹⁴

Current CHP in the United States

CHP is an important electric generating resource in the United States. Currently, over 82.7GW of CHP capacity exists at over 4,400 industrial and commercial facilities across the country.¹⁵ This represents 8% of U.S. electricity generation capacity, however it represents over 12% of annual U.S. power generation, reflecting the longer operating hours of CHP systems as compared to conventional forms of generation.

CHP systems are installed in every state, however there are significant regional differences in the distribution of CHP sites and capacity. Some states have adopted policies that encourage CHP growth, most notably California, New York and Connecticut, which offer financial and other incentives to CHP projects. Other regional variations come from electricity price variations, energy market structures, and industrial development. For example, chemicals and refining facilities are common in the Gulf Coast states and paper production in the Southeast. States with higher overall energy demand, more energy-intensive industry, and dense population centers with concentrated electricity and thermal energy demand naturally have the highest amounts of CHP capacity.

Figure I-2 displays the distribution of existing CHP capacity by state.

¹⁴ For more information, please visit the DOE CHP TAPs website at www.energy.gov/chp-contacts.

¹⁵ DOE CHP Installation Database (U.S. installations as of December 31, 2014). www.energy.gov/chp-installs

Figure I-2: Existing CHP Capacity by State

Source: DOE CHP Installation Database (U.S. installations as of December 31, 2014)

CHP can be utilized in a variety of industrial facilities and commercial buildings with coincident power and thermal loads. **Figure I-3** presents a breakdown of CHP capacity by major market sector. The majority of existing CHP capacity in the United States is in the industrial sector and is concentrated in five major facility types: chemicals, refining, paper, food and metals manufacturing.

Figure I-3: Existing CHP Capacity in the United States by Facility Type¹⁶

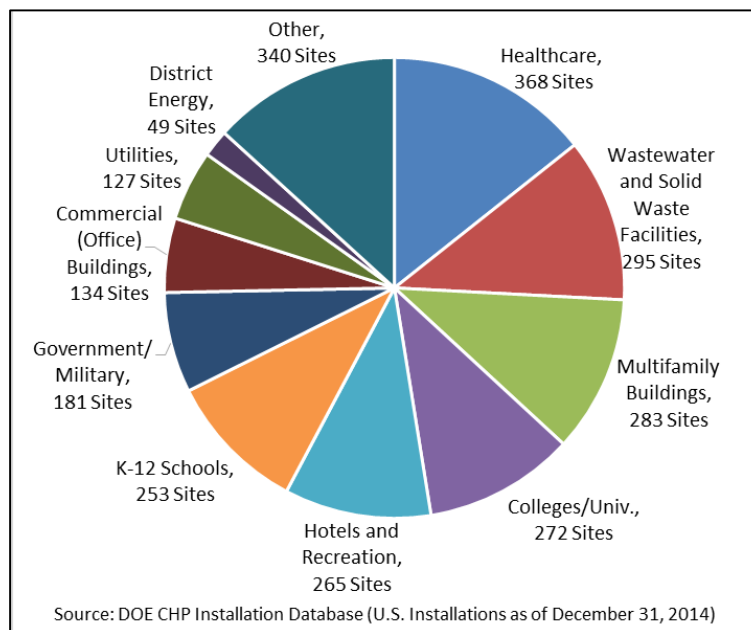

Source: DOE CHP Installation Database (U.S. installations as of December 31, 2014)

¹⁶ The Other Manufacturing category includes textiles, lumber and wood, transportation equipment, rubber and plastics, stone/clay/glass, machinery, instruments, electronics, and miscellaneous manufacturing.

Commercial and institutional buildings make up the remainder of existing capacity. Commercial CHP systems are typically located in larger facilities such as waste water treatment plants, hospitals, colleges and universities, and military campuses, but they can also produce power and heat for multi-family buildings, hotels, offices, retail stores, recreational facilities, K-12 schools, and nursing homes. CHP installations in commercial facilities make up 58% of CHP sites in the U.S. but account for only 14% of capacity¹⁷. This is due to the relatively small size of these facilities, which are typically much smaller than industrial facilities. Commercial building types in the services sector are seen as potential growth markets for CHP in the U.S. The U.S. Department of Energy and CHP equipment manufacturers have both invested in technology improvements for small plants, focusing on increasing efficiency, incorporating new thermally activated technologies to provide both heating and cooling services, and integrating components and controls into cost effective packages.¹⁸

Figure I-4 shows existing commercial CHP by number of sites. Site installations are relatively evenly distributed between the major commercial business types for CHP, including healthcare, waste water and solid waste facilities, multifamily buildings, and colleges/universities. However, the amount of capacity installed in commercial business types varies widely, as shown in **Figure I-5**. Colleges and universities, district energy facilities, and municipal utilities often install larger systems compared to other commercial business types, and they represent a significant portion of existing commercial CHP capacity. Commercial facilities such as office and multifamily buildings, schools, and hotels have many existing site installations, however these systems are typically smaller around a few hundred kilowatts in size.

This CHP technical potential report will discuss the typical industrial facilities and commercial buildings that support both traditional “topping cycle” CHP and “bottoming cycle” or waste heat to power CHP (WHP CHP) and district energy CHP. The goal of the report is to provide data on the technical potential for CHP in sufficient detail for stakeholders to consider combined heat and power in strategic energy planning and energy efficiency program design. Data are provided nationally by CHP system size range, facility type, and location. Each state’s technical potential is also delineated by these characteristics. The report is organized as follows:

- **Facilities Where CHP is a Potential Opportunity** – This section describes the industrial and commercial sectors that are best suited for utilizing CHP. Profiles of successful CHP installations are included for each CHP type that is evaluated.
- **Technical Potential – National Results** – This section provides overall national level results on the amount of CHP technical potential that exists for each CHP type, including on-site industrial, on-site commercial, on-site WHP CHP, industrial export, and district energy export.
- **Technical Potential – State Results** – The state results section provides detailed information on the technical potential in each state, with summary statistics, charts, and tables providing insight into each state’s specific market opportunities.
- **Conclusions** – This section brings together the results of the technical potential analysis and compares them to the amount of existing CHP installed in the U.S. to place the potential estimates into context.
- **Appendices** – Appendix A includes the methodology for calculating the CHP technical potential. Appendix B includes power to heat ratios by facility type. Technical potential results by 4-digit NAICs codes are provided in Appendix C for select industries. Appendix D provides more detailed state-specific breakdowns of CHP technical potential.

II. Facilities Where CHP is a Potential Opportunity

Combined heat and power can be utilized in a variety of industrial facilities and commercial buildings with coincident power and thermal loads. This study considers both traditional “topping cycle” CHP and “bottoming cycle” or waste heat to power CHP (WHP CHP). Topping cycle CHP systems are the most common CHP systems currently in use. In a topping cycle system, fuel is first combusted to generate electricity. A portion of the heat left over from the electricity generation process is then used to provide useful thermal energy (e.g. heating/cooling, hot water, or steam for industrial processes). A bottoming-cycle CHP system, which will be referred to as WHP CHP in this report, uses the reverse process. Fuel is first combusted to provide thermal input to industrial process equipment like a kiln or furnace, and the heat rejected from the process is then captured and used for power production.

Industrial Facilities

Facilities in the industrial sector currently represent about 86% of existing CHP capacity in the United States. There are over 1,200 existing industrial CHP facilities totaling about 66GW of capacity.¹⁹ Industrial sites often require large CHP systems (>20MW in nameplate capacity) because of their high thermal and electric loads. The installation of large CHP projects greater than 20MW has declined in recent years. However, as natural gas prices have decreased and in many regions and electricity rates have increased, CHP is being reconsidered by facility owners. Interest in biomass and other alternative fuels is also increasing in areas where natural gas is either too costly or not available. **Table II-1** provides a list of the types of industrial facilities considered in this report.

Table II-1: Types of Industrial CHP Facilities

SIC	NAICS	Industrial Facility Type
20	311	Food & Beverage
22	313	Textiles

¹⁹ DOE CHP Installation Database (U.S. Installations as of December 31, 2014.) www.energy.gov/chp-installs

Top Types of Industrial Facilities Conducive to CHP Opportunities

Examples of industrial facilities that are a good fit for CHP due to their high coincident power and thermal loads include food processing, chemicals, refining and metal manufacturing.

- **Food Processing:** Food processing plants have a diverse range of power and thermal needs. CHP systems at these facilities range from large systems at grain or meat processing centers to smaller systems at local breweries or bakeries. The majority of systems are natural gas-fired and use boiler/steam turbines or reciprocating engines as prime movers.
- **Chemicals:** The chemical manufacturing sector is the second largest consumer of energy in the industrial market. Waste heat captured from power production can be used in an array of chemical manufacturing processes. CHP systems at chemical facilities are typically large (the average size is 80MW). The majority are natural gas-fired and use boiler/steam turbines, or combined cycles as prime movers.
- **Refining:** The refining industry is the largest energy consuming industrial group in the United States. Petroleum refineries have large on-site power and thermal demands for process heat and steam tracing (to keep pipes warm). Most CHP systems at refining facilities are large (the average size is 153MW). Most of these systems are natural gas-fired and use combined cycles or combustion turbines as prime movers.
- **Metals Manufacturing:** Metal manufacturing facilities can have large power and steam demands for equipment like electric arc furnaces and processes such as heating dip tanks and chemical baths. The average size of a CHP system at a metals facility is 65MW. The majority of systems are fueled by natural gas or waste products, and use boiler/steam turbines as prime movers.
- **Paper:** Paper processing facilities can have large power demands, as well as large and consistent thermal demands for steam, which is typically used for cooking pulp and drying paper. Paper plants also tend to produce byproducts like black liquor that can be used as a fuel for a CHP system. The average CHP system at a paper manufacturing facility is

Successful CHP Installations

Food Processing: At the Frito-Lay manufacturing plant in Killingly, CT, a 4.6MW CHP system provides over 90% of the plant's electrical demand and 80% of the plant's steam load. The plant can operate in island mode and saves the facility about \$1 million/year in energy costs.²⁰

Metals: Kennecott Utah Copper's plant outside of Salt Lake City has a CHP system that produces more than half of the facility's power needs, as well as captured heat that is turned into process steam for the facility's chemical baths, which turn copper anodes into cathodes.²¹

²⁰ Frito-Lay Project Profile, http://www.energy.gov/sites/prod/files/2015/08/f26/PepsiCo%20Frito-Lay%20CHP%20Case%20Study_07.02.15.pdf

²¹ Kennecott Utah Project Profile, http://www.southwestchptap.org/data/sites/1/documents/profiles/Kennecott_Utah_Copper_Refinery-Project_Profile.pdf

50MW. Most systems are fueled by waste products, coal, or natural gas, and the majority use boiler/steam turbines as the prime mover.

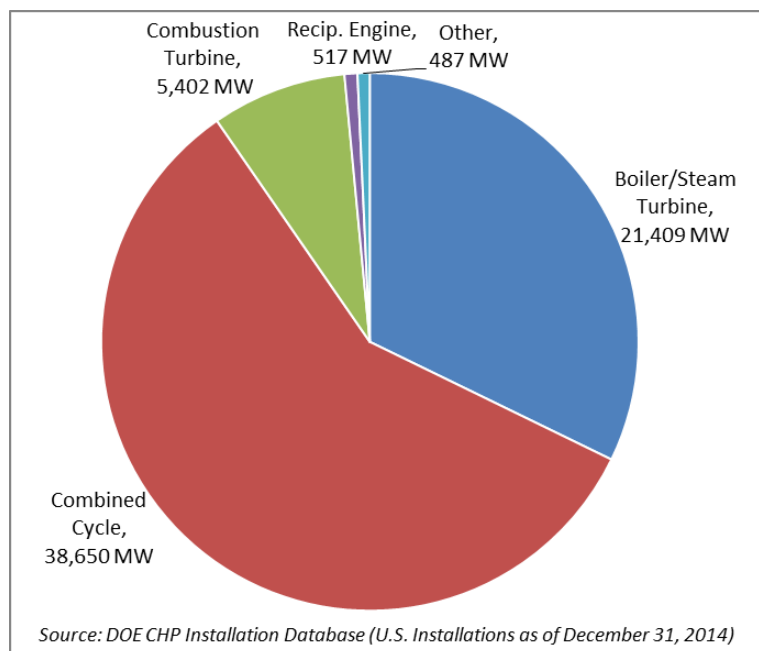

CHP Sizing for Industrial CHP

The measure of average industrial CHP size is skewed upward by very large installations at the upper end of the range: hence, the average system size of currently installed industrial CHP in the U.S. is approximately 53MW, while the median size is much lower at 7MW.²² The optimal way to size a CHP system for a facility is by matching the thermal output of the system to the baseload thermal demand of the facility. Some industrial facilities have thermal loads that exceed their electric demands, and can thereby export excess power to the grid. Additional information about CHP sizing is provided in Appendix A: Technical Potential Estimation Methodology.

Technologies and Fuel Types for Industrial CHP

Boiler/steam turbines and reciprocating engines are the most frequent prime mover choices for industrial CHP customers, making up 43% and 21% of installations respectively. Combined cycles²³ make up only 12% of industrial CHP installations; however, they make up the majority of industrial CHP capacity at 58%. Boiler/steam turbine systems, which represent 32% of total CHP capacity, are typically fueled by solid fuels such as coal and wood waste, whereas combustion turbines and reciprocating engines are typically fueled by natural gas. **Figure II-1** presents the distribution of prime mover technologies by capacity in the industrial sector.

Figure II-1: Existing Industrial CHP Capacity by Prime Mover²⁴ (66,465 MW)

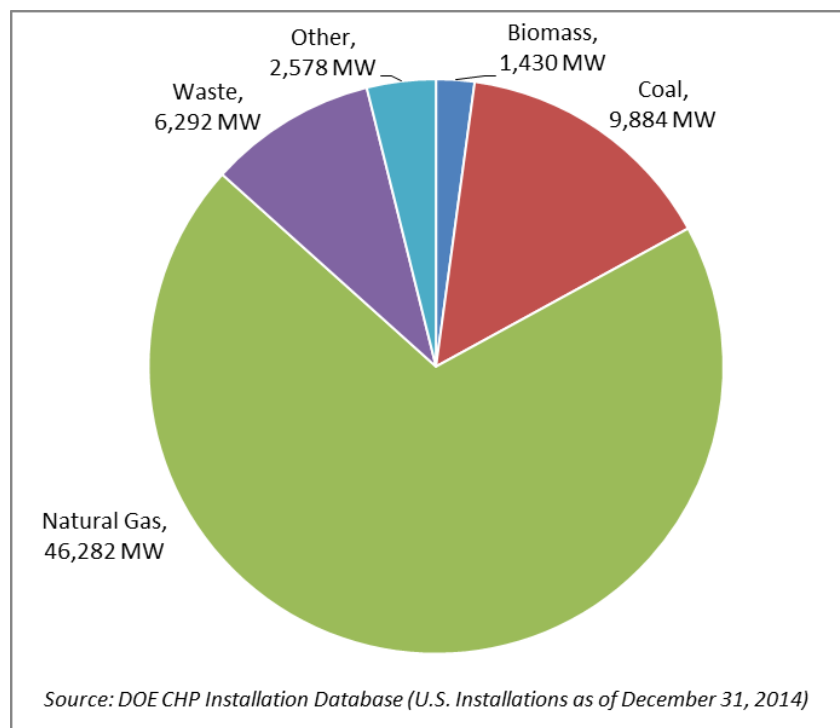

²² DOE CHP Installation Database (U.S. installations as of December 31, 2014) www.energy.gov/chp-installs

²³ Combined cycle systems are a combination of a combustion turbine and a steam turbine. When used for CHP, steam is typically extracted from the steam turbine at the temperature and pressure required by a process.

²⁴ Other industrial prime movers include fuel cells, microturbines, and waste heat to power technologies.

Figure II-2 shows the distribution of CHP capacity by fuel type used in the industrial sector. Natural gas makes up the majority of both industrial installations and capacity (over 670 installations and 46GW of capacity use natural gas). Given the widespread availability of natural gas, lower per-unit costs, and the frequency that gas combustion turbines and combined cycles are used in industrial CHP systems, it is not surprising that natural gas fuels the majority of industrial capacity and installations. Additionally, air quality and emissions compliance regulations tend to favor natural gas over other fossil fuels, especially in dense urban locations. However, interest in biomass and alternative fuels is increasing in facilities or locations where natural gas is less readily available or more costly. Biomass and biofuels, which make up about 2% of installed capacity, are most frequently used in industries such as food and paper processing, where viable and reliable on-site biogas and biomass resources can be used to produce power.

Figure II-2: Existing Industrial CHP Capacity by Fuel Class²⁵ (66,465 MW)

Commercial, Institutional, and Multifamily Buildings

There are currently over 2,500 existing commercial, institutional, and multifamily (herein referred to collectively as commercial) CHP installations in the U.S., totaling over 11.5GW of capacity.²⁶ These installations are typically smaller than those at industrial sites; commercial buildings represent only about 14% of existing CHP capacity, but over 57% of existing CHP sites. Commercial buildings represent the strongest potential growth markets for CHP. Several of these

²⁵ Other industrial fuel types include oil and wood. Waste fuel types include black liquor, blast furnace gas, municipal solid waste, other gas, petroleum coke, waste fluid, and waste heat.

²⁶ DOE CHP Installation Database (U.S. Installations as of December 31, 2014.) www.energy.gov/chp-installs

building types have more CHP potential than existing CHP, including but not limited to: retail stores, commercial and multifamily buildings, hotels, and colleges/universities. These building types provide an opportunity to use standardized packaged CHP systems in replicable installations at multiple facilities throughout the country that are owned by the same organization. Some commercial buildings, such as data centers, supermarkets, and refrigerated warehouses, have high and stable demands for space cooling that are good fits for CHP paired with absorption chillers. **Table II-2** provides a list of all commercial building types considered in this report.

Table II-2: Commercial CHP Building Types

Top Types of Commercial Buildings Conducive to Combined Heat and Power Opportunities

Unlike industrial facilities, which have consistent thermal and electric demands, commercial buildings typically exhibit seasonality in on-site power and thermal needs. Thermal needs in the commercial sector include space heat, space cooling, and water heating. Examples of commercial buildings most suitable for CHP include those with year-round thermal needs such as waste water treatment facilities, hospitals, multifamily buildings, colleges and universities, and military campuses.

- **Waste Water Treatment:** Waste water treatment plants that have anaerobic digesters and operate 24 hours a day are prime candidates for CHP. Most CHP systems at waste water treatment plants are between 100kW – 10MW. The majority are fueled by biomass or natural gas, and use combustion turbines or reciprocating engines as prime movers.
- **Hospitals:** Hospitals have the coincident electric and thermal loads that match CHP capabilities and drive project economics. Hospitals need continuous power and have a large demand for domestic hot water, sterilization and laundry. In addition, hospitals are considered critical facilities in the event of a natural disaster or emergency, so the backup reliability of CHP is a good match for their needs. Most CHP systems at hospitals are 5MW or smaller. The vast majority are fueled by natural gas and use reciprocating engines or combustion turbines as prime movers.
- **Multifamily:** Multifamily buildings have high needs for hot water and space conditioning (location dependent). Most CHP systems at multifamily buildings are smaller (~100kW), compared to their other commercial and industrial counterparts. They are typically fueled by natural gas and use reciprocating engines or microturbines as the prime mover.
- **Colleges/Universities:** Similar to hospitals, colleges and universities have coincident power and thermal loads that are often optimal for CHP systems. The typical college or university campus has a high thermal load for conditioning dormitories, classrooms and research labs. These systems are often served by central utility plants with chilled water and steam or hot water distribution systems. The average college or university CHP system is about 10MW. The majority are fueled by natural gas and use boiler/steam turbines, combustion turbines, or reciprocating engines as prime movers.

Successful CHP Installations

Waste Water Treatment: The Danville Sanitary District in Danville, Illinois has a 150kW CHP system that offsets about 20% of the facility's electric use and almost 100% of the facility's natural gas needs.²⁷

Multifamily: The 75kW CHP system installed at the Boa Vista Apartments in New Bedford, Massachusetts provides electricity, hot water, and space heating to the multifamily building, and it has reduced the building's annual energy costs by 43%. The simple payback for the system was less than 4 years, which exceeded initial estimates.²⁸

Military: In 2014, Fort Knox deployed three CHP systems on campus that provide a total of 8MW of power. The locations for each system, a hospital, a data center, and a retail center, were chosen for being critical infrastructure facilities and for being prime locations for the thermal loads produced by the systems.²⁹

²⁷ Danville Sanitary District Project Profile, <http://www.midwestchptap.org/profiles/ProjectProfiles/Danville.pdf>

²⁸ Tecogen Brevoort case study, <http://www.tecogen.com/resources-case-studies.htm> Boa Vista Apartments Project Profile, <http://northeastchptap.org/data/sites/5/documents/profiles/boavistachp.pdf>

²⁹ Fort Knox Project Profile, http://southeastchptap.rlmartin.com/Data/Sites/4/documents/profiles/fort-knox-chp_project_profile.pdf

- **Military Bases:** Much like colleges, military base CHP systems are typically installed at sites with large campuses that have a significant power and thermal loads for barracks, office buildings, training facilities, medical centers, and other staff support buildings. Military bases are also often served by a large central plant that enables easier CHP integration. CHP systems on military campuses range in size from a few kilowatts to several dozen megawatts, though most systems are under 20MW. The majority of systems are natural gas-fired and use boiler/steam turbines or reciprocating engines as prime movers.

Some commercial buildings, such as hospitals, military campuses, data centers, supermarkets, office buildings, and multifamily buildings, have high and stable demands for cooling. These buildings can be served using a CHP system with an absorption chiller that uses the heat from the CHP system to generate chilled water.

- **Data Centers:** Data centers require high quality, reliable power and have large thermal loads for space cooling. CHP systems at data centers range in size from a few hundred kilowatts up to 10MW. The majority are fueled by natural gas and use microturbines as prime movers.
- **Supermarkets:** Refrigeration and lighting are the two largest electricity loads in the supermarket industry, creating a good fit for CHP, which can provide the electricity and chilling needed to satisfy these energy demands. CHP systems at supermarkets are typically on the small side (<1MW). Most systems are fueled by natural gas and use reciprocating engines as prime movers.
- **Office Buildings:** Office buildings have thermal loads that vary seasonally. CHP systems can be designed to utilize heat in the winter months and use an absorption chiller for cooling in the summer months. The majority of CHP systems at office buildings are under 2MW, though some larger systems do exist. The majority of

Successful CHP Installations

Data Centers: Syracuse University installed a microturbine CHP system with a 300-ton absorption chiller, which provides power, heating and cooling to the university's Green Data Center.³⁰

Supermarkets: Waldbaum's Supermarket in Hauppauge, NY, installed a 60kW microturbine CHP system in 2002. The system provides power, heating, cooling, and dehumidification to the supermarket.³¹

Office Buildings: The Brandonview Building (formerly the Laclede Gas Building), in St Louis, MO, has a 4.3MW CHP system that provides 100% of the building's power. A 1,050 ton absorption chiller is integrated with the CHP system to provide summer cooling to the building, which has not had an unplanned power outage since 1980.³² CHP system

³⁰ Syracuse University Project Profile, http://www.northeastchptap.org/Data/Sites/5/documents/profiles/Syracuse%20Case%20Study_Final.pdf

³¹ Waldbaum's Supermarket Project Profile, http://www.northeastchptap.org/Data/Sites/5/documents/profiles/Waldbaums_CHPProjectProfile.pdf

³² Brandonview Building Project Profile, [http://www.midwestchptap.org/profiles/ProjectProfiles/Brandonview\(Laclede%20Gas\).pdf](http://www.midwestchptap.org/profiles/ProjectProfiles/Brandonview(Laclede%20Gas).pdf)

systems are fueled by natural gas and use reciprocating engines as prime movers.

CHP Sizing for Commercial CHP

CHP systems at commercial buildings are typically smaller than their counterparts at industrial facilities, but as in industrial facilities, average sizes are skewed upward by a relatively small number of large installations. The average size of existing commercial installations in the U.S. is about 4.5MW, while the median size is only 300kW.³³ Sizing a CHP system to commercial sites follows the same methodology as for industrial sites (i.e. sizing the CHP system to the thermal load.). However, the thermal load will rarely exceed electric demand like in some industrial plants, so in most cases, the system will not need to be limited to match on-site power needs. Thus, the key difference for commercial buildings is that these sites will not typically export power, and they will frequently require supplemental utility electricity during hours of operation.

The technical potential analysis section of this report sets the minimum size for commercially available CHP at 50kW.³⁴ CHP technologies below 50kW have had wide success in other countries; however, they are not common in the U.S. and therefore are not considered in the analysis for this report.

Technologies and Fuel Types for Commercial CHP

Though reciprocating engines make up only 13% of installed commercial CHP capacity, they are the most popular choice for commercial CHP buildings, representing about 67% of all commercial units in the United States.³⁵ Many large commercial CHP systems have multiple units installed to boost capacity. This is due to the fact that some prime mover technologies, such as reciprocating engines and microturbines, are packaged at predetermined capacities that may not meet the full needs of the facility. Installing multiple units is a way for a facility to meet their thermal requirements in a cost-effective way, and it allows for a measure of flexibility when operating the system. Prime movers with larger portions of commercial CHP capacity (boiler/steam turbines, combined cycles and combustion turbines) can be found at commercial buildings that have higher electric and thermal demands. These commercial buildings include hospitals and colleges/universities. **Figure II-3** represents the distribution of commercial CHP capacity by prime mover type.

³³ DOE/ICF CHP Installation Database (U.S. installations as of December 31, 2014) www.energy.gov/chp-installs

³⁴ Reciprocating engines in the lower size range from 10 – 50 kW are commercially available for use as backup generators, but are not typically used in conjunction with heat recovery equipment as CHP systems.

³⁵ DOE/ICF CHP Installation Database (U.S. installations as of December 31, 2014) www.energy.gov/chp-installs

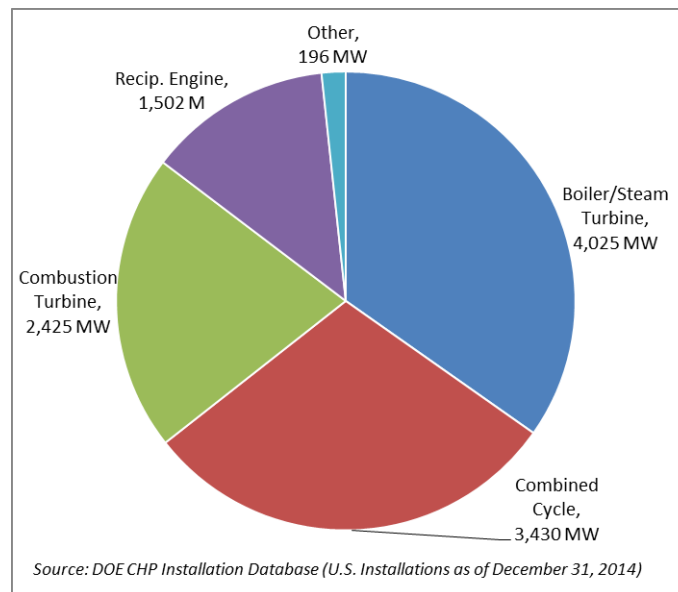

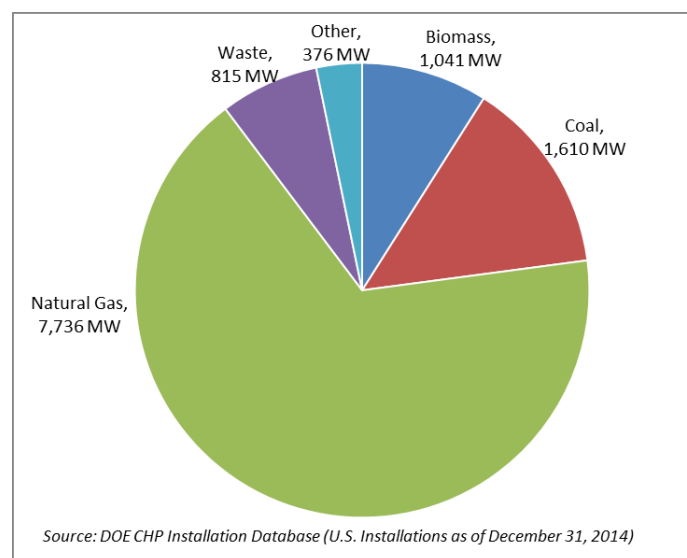

Figure II-3: Existing Commercial CHP Capacity by Prime Mover³⁶

Figure II-4 presents the distribution of commercial CHP capacity by fuel type. Natural gas is the most common fuel type used for CHP in commercial buildings. Natural gas serves as the primary fuel for 75% of commercial CHP installations (over 1,900 installations) and accounts for 67% of capacity (7.7GW). Biomass and waste also make up significant portions of both installations and capacity, being common fuels for use at waste water treatment and solid waste facilities. Three commercial building types use 87% of the coal burned in commercial CHP systems: utilities, district energy systems, and universities.

Figure II-4: Existing Commercial CHP Capacity by Fuel Class³⁷

³⁶ Other commercial prime movers include fuel cells, microturbines, and waste heat to power technologies.

³⁷ Other commercial fuel types include oil and wood. Waste fuel types include municipal solid waste, other gas, waste fluid, and waste heat.

Waste Heat to Power CHP

Waste heat to power (WHP CHP) is the process of capturing heat discarded by an existing thermal process and using it to generate electricity. There is currently 469MW of existing WHP CHP capacity distributed among 75 sites across the country. The majority of this capacity is located within the primary metals (217MW) and refining (118MW) applications. **Figure II-5** shows the existing WHP CHP capacity in the U.S. by facility type.

Figure II-5: Existing WHP Capacity by Facility Type

Top Types of WHP Facilities Conducive to Combined Heat and Power Opportunities

The top facility types suitable for WHP CHP systems are market sectors with large waste heat streams available for capture at temperatures conducive to generating electric power. These market sectors are typically industries such as refining, chemicals, and metals manufacturing.

- Refining:** Petroleum refineries, the largest user of energy in the industrial sector, can produce high-quality waste heat that can be recovered for power production in a bottoming-cycle CHP system. One example of this high-quality waste heat is the exhaust from petroleum coke calciners.
- Chemicals:** Chemical manufacturing can produce a significant amount of waste heat that has the potential to be converted to power. Petrochemicals, industrial gases, and synthetic organic fibers are all examples of chemical manufacturing sectors that produce enough waste heat to make WHP CHP feasible.

Successful WHP CHP Installations

Refining: At a petroleum coke plant in Texas, Port Arthur Steam Energy recovers heat from three petroleum coke calcining kilns to produce steam for process use and 5MW of electric power.³⁸

Metals: Cokenergy, LLC, owns and operates a WHP CHP system at the ArcelorMittal steel plant in East Chicago, IN. The system has a generating capacity of 95MW, and provides steam for process heating and electricity to the ArcelorMittal plant.³⁹

³⁸ Port Arthur Steam Energy case study, Port Arthur Steam Energy Project Profile, http://www.southwestchptap.org/data/sites/1/documents/profiles/Port_Arthur_Steam-Project_Profile.pdf

³⁹ Cokenergy Project Profile, <http://www.midwestchptap.org/profiles/ProjectProfiles/Cokenergy.pdf>

- *Metals Manufacturing:* Several metals manufacturing facilities have high temperature processes from which waste heat can be recovered for a WHP CHP system. Iron and steel mills, aluminum production, and fabricated metals manufacturing are all good candidates for WHP CHP.

District Energy CHP

District energy systems produce and deliver steam, hot water or chilled water through underground piping networks to buildings in a given area, such as a college campus or downtown city centers. By combining individual user thermal loads, district energy systems can potentially deliver energy services in a more efficient, economic, and environmentally friendly manner. Though district energy systems aggregate thermal loads of multiple customers, they cannot always provide electricity to the same customers because of utility franchise laws. District energy systems are not always integrated with CHP systems; however, combining district energy with a CHP system can be a unique opportunity to provide both thermal and power, serving multiple customers and energy needs at once. *This analysis of potential for CHP at district energy facilities only applies to existing district energy systems that do not currently have CHP or existing district energy systems with CHP that have room for expansion. This analysis does not examine the potential for new district energy systems in the United States.*

Top Types of District Energy Facilities Conducive to Combined Heat and Power Opportunities

District energy CHP systems are most viable in loops that have multiple thermal hosts, such as a large college or university campus, or an urban center with a variety of customers. These are key targets for CHP because they represent a large portion of existing district energy capacity in the United States. According to the International District Energy Association (IDEA), there are over 400 existing district energy systems in the United States.⁴²

- *Colleges/Universities:* IDEA currently estimates that there are about 220 district energy systems on college and university campuses that do not incorporate CHP and 136 systems that do. Colleges and universities have large thermal demands that make district energy

Successful District Energy with CHP Installations

Colleges/Universities: The University of North Carolina at Chapel Hill has an integrated CHP and district energy system that supplies power, chilled water, and district heating and cooling to buildings on campus. In addition, UNC uses district heating and cooling at the UNC Hospital.⁴⁰

Downtown Loops: District Energy St. Paul, is a prominent example of a downtown loop that successfully integrated CHP into the existing district energy system. The CHP system uses wood waste from local sources as fuel and provides up to 33MW of electric power to the local utility, as well as heating and cooling to an array of commercial and residential customers in downtown St. Paul.⁴¹

⁴⁰ University of North Carolina-Chapel Hill Project Profile,

http://southeastchptap.rlmartin.com/Data/Sites/4/documents/profiles/unc-chp_project_profile.pdf

⁴¹ District Energy St. Paul website, <http://www.districtenergy.com/technologies/combined-heat-and-power/>

⁴² District Energy Fact Sheet, IDEA 2011. <http://www.districtenergy.org/assets/pdfs/White-Papers/What-IsDistrictEnergyEESI092311.pdf>

systems a practical choice for distributing steam around campus. By incorporating CHP, colleges and universities can increase their efficiency, generate their own power, and capture more waste heat to serve their thermal needs.

- *Downtown Loops:* Downtown loop district energy systems typically provide steam to a variety of customers in a downtown city center, such as commercial office buildings, downtown hospitals, museums, and residential areas. There are over 40 downtown loop district energy systems without CHP and over 35 with CHP systems.⁴³ By incorporating CHP, district energy systems can provide power in addition to meeting the thermal needs of their customers.

⁴³ IDEA – International District Energy Association. <http://www.districtenergy.org/map-of-district-energy-in-north-america>

III. Technical Potential - National Results

This section provides estimates of the technical potential for combined heat and power in the industrial and commercial sectors in the United States. The technical potential is an estimation of market size constrained only by technological limits — the ability of CHP technologies to fit customer energy needs. CHP technical potential is calculated in terms of CHP electrical generation capacity that could be installed at existing industrial and commercial facilities based on the estimated electric and thermal needs of the site. The technical potential is useful in understanding the potential size and distribution of the CHP market in a particular region. Identifying the technical market potential is a preliminary step in the assessment of the economically feasible market size and ultimate market penetration for CHP.

The determination of technical potential consists of the following elements:

- Identification of target markets where CHP provides a reasonable fit to the electric and thermal needs of the user.
- Quantification of the number and size distribution of target markets. Several data sources were used to identify the number of candidate facilities in each target market that meet the electric and thermal load requirements for CHP.
- Estimation of CHP potential in terms of MW electric capacity. CHP potential is derived based on the thermal and electric load for typical sites by facility type and size range. Total CHP potential for each target market is then calculated by the amount of CHP potential in each size category.
- Subtraction of existing CHP from the identified sites to determine the remaining technical potential.

Three different types of CHP are evaluated in this analysis: traditional topping cycle CHP, WHP CHP (sometimes referred to as bottoming cycle CHP), and district energy CHP.

Across all CHP categories, there is an estimated 240.6GW of technical potential at over 291,900 sites within the U.S. **Table III-1** shows the breakdown across the various system types. Traditional topping cycle CHP has the most overall potential with 222GW (141GW of industrial and commercial on-site and 81GW export). Waste heat to power CHP has about 7.6GW of potential nationwide, and district energy has 10.6GW⁴⁴, both almost entirely concentrated at sites with technical potentials greater than 20MW. Overall, the 240.6GW of CHP technical potential in the United States is almost three times the amount of capacity that is currently operational (82.7GW), meaning there is significant potential for increased deployment of CHP.

⁴⁴ This 10.6GW of potential is only for existing district energy systems that do not employ CHP or have the ability to expand an existing CHP system. An analysis of the potential for new district energy systems was not conducted.

Table II-1: Total CHP Technical Potential across All Facility Types

Business Type	50-500kW		0.5 - 1 MW		1-5 MW		5-20 MW		>20 MW		Total Sites	Total Capacity (MW)
	# Sites	Capacity (MW)	# Sites	Capacity (MW)	# Sites	Capacity (MW)	# Sites	Capacity (MW)	# Sites	Capacity (MW)

U.S. DOE CHP Deployment Program, 2016.

Figure III-1 shows the total on-site technical potential in each state. States with the most technical potential include densely populated states with large manufacturing sectors, such as California, Texas, Ohio, Pennsylvania, New York, and Illinois. The least amount of technical potential is found in rural states in the Northwest and northern New England regions.

Figure III-1 : On-site Technical Potential by State

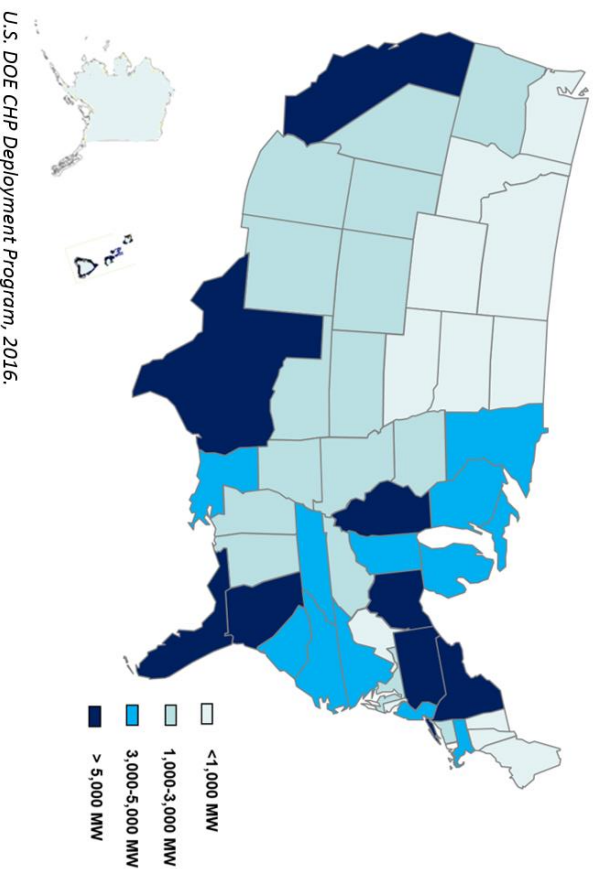

Table III-2 shows the breakdown of on-site and export technical potential for each state. On-site potential includes industrial, commercial and WHP potential, while export potential includes industrial export and district energy potential. There is an estimated 149GW of on-site and WHP potential across all states, and 92GW of incremental export and district energy potential.

Table III-2: Total On-Site and Export Technical Potential Across all States

State	Total On-site Potential (MW)	Total Export Potential (MW)	Total CHP Technical Potential	State	Total On-site Potential (MW)	Total Export Potential (MW)	Total CHP Technical Potential

U.S. DOE CHP Deployment Program, 2016.

On-site CHP Technical Potential Results

The total U.S. on-site CHP potential, which includes industrial and commercial topping cycle CHP and WHP CHP, is just under 149GW. **Table III-3** and **Table III-4** display industrial and commercial potential by facility type. The industrial sector has 73GW of on-site technical potential and the commercial sector has 76GW. Significant markets include chemical manufacturing, paper processing, commercial office buildings, and universities. **Table III-5** displays industrial and commercial on-site technical potential by state. Top states with high technical potential in both the industrial and commercial sectors include California, Illinois, New York, Ohio, Pennsylvania and Texas. These states have large manufacturing sectors (chemicals and refining in Texas, for example) with high CHP technical potential. They also have large cities with many opportunities for CHP at commercial and multifamily buildings as well as high concentrations of colleges and universities.

CHP Export Technical Potential Results

Table III-6 shows total CHP export technical potential by facility type. This potential represents a CHP unit sized to meet the thermal load, with the facility selling excess electricity back to the grid. Industrial facilities and downtown district energy systems are assumed to be the only facility types that produce export electricity for this analysis. CHP systems provide the most benefit when sized to meet all of the thermal demand of a given facility. Maintaining optimal system efficiency in this scenario requires that more electricity be generated than can be used on-site⁴⁵. This excess electricity could then be exported back to the grid. Total export CHP technical potential is estimated at 92GW. Most of the export potential is found in the refining, paper, chemicals, district energy, and food industries because of the high thermal loads relative to on-site electric demand.

Table III-6: U.S. Industrial and District Energy Export Technical Potential

		Total	0	7	3,947	11,610	76,145	91,709

U.S. DOE CHP Deployment Program, 2016.

The potential to export electricity to the grid is not evenly distributed throughout the country, but is more heavily concentrated in states with large industrial facilities and existing district energy systems. Texas has the most export potential due to its significant chemical and petrochemical facilities, followed by other large industrial states like California, Louisiana, Illinois, and New York.

⁴⁵ By nature, downtown district energy systems serve multiple customers. Electricity cannot be sold to multiple customers unless the seller is an electric utility. Therefore, any electricity produced by CHP systems serving downtown district energy loops is assumed to be exported to the grid.

Table III-7 shows the export technical potential segmented by state.

Waste Heat to Power CHP Technical Potential Results

Total U.S. WHP CHP technical potential is estimated to be 7.6GW across all facility types and waste heat streams. **Table III-8** displays the WHP technical potential and number of sites in the United States by target market. Petroleum, metal, and non-metallic mineral markets contain the highest amount of technical potential. These four facility types represent 91% of the total technical potential within the U.S. These figures represent the amount of remaining technical potential at each site because existing WHP CHP capacity was subtracted from the total amount of technical potential.

District Energy CHP Technical Potential Results

This analysis of potential for CHP at district energy facilities only applies to existing district energy systems that do not currently have CHP or existing district energy systems with CHP that have room for expansion. This analysis does not examine the potential for new district energy systems in the United States.

Table III-10 displays the total technical potential for district energy systems by size range. The table is divided in two categories to show the potential for district energy loops that do not currently include CHP systems and the potential to expand existing CHP systems serving district energy systems. In total, 10.6GW of technical potential was identified at 64 existing downtown and district energy loops across the nation. The vast majority of district energy CHP potential is found in the >20MW size bin, which contains 51 of the systems and 10.5GW of the total 10.6GW. District

⁴⁷ Also known as Bottoming Cycle CHP, this is a subset of Total CHP Technical Potential

energy systems greater than 20MW will often be large, downtown district energy systems serving multiple customers in a geographical area.

Table III-10: Total U.S. District Energy Technical Potential by Size Range⁴⁸

SIC	NAICS	District Energy Type	1-5 MW		5-20 MW		>20 MW		Total Sites	Total Capacity (MW)
			# Sites	Capacity (MW)	# Sites	Capacity (MW)	# Sites	Capacity (MW)		
4961	221	Current Loops without CHP	3	10	5	51	27	3,055	35	3,116
4961	221	Current Loops with CHP Expansion	2	8	3	24	24	7,511	29	7,543
		Total	5	18	8	75	51	10,567	64	10,660

U.S. DOE CHP Deployment Program, 2016.

Table III-11 shows the breakdown of technical potential for district energy systems by size range and state. The first two size bins (50-500kW and 500-1,000kW) were left out of the table due to a lack of systems in this size range. This table shows that New York has the most potential capacity for CHP at district energy systems, mainly due to the CHP capacity that could be added to the district energy system that serves New York City. Other states with high amounts of technical potential are Minnesota, Pennsylvania, and Michigan. Each of these states has large cities that are served by district energy systems where CHP could be installed or expanded.

⁴⁸ This is a subset of Total CHP Technical Potential

IV. Technical Potential - State Results

The national CHP technical potential is distributed unevenly among the 50 states and the District of Columbia, with the more populous and industrial states containing more technical potential than other states. The following state profiles provide information and data on the state-specific technical potential for industrial CHP, commercial CHP, waste heat to power (WHP) CHP, and district energy CHP. They are intended to provide an overview of the full technical potential for CHP in each state and can serve as a reference to stakeholders considering CHP as an energy efficiency solution in their jurisdiction.

State Profile Format

The state profiles are organized by CHP technical potential category for easy reference. The first section of each profile includes an overview of CHP potential by sector in each state. Next, two charts show the major facility types for both industrial on-site CHP and commercial CHP technical potential.⁴⁹ These charts serve as an indicator of where the most CHP technical potential exists in each state. Finally, the state profiles include two tables on the identified waste heat to power and district energy CHP potential in each state. The waste heat to power technical potential is organized by facility type, while the district energy CHP potential shows the available CHP potential in downtown loops that do not have existing CHP systems as well as downtown loops that have room for expansion of their current CHP system.

These state profiles are intended as a starting point to understand the CHP technical potential market at the state level. Additional information on CHP technical potential in each state is available in Appendix D. This includes a summary of overall CHP technical potential as well as detailed breakouts on the number of sites and capacity identified in each target facility type.

⁴⁹ Note that the state profile pages do not include information about export potential.

Alabama

Alabama has 2,777 MW of CHP technical potential capacity identified at 4,512 sites.⁵⁰

Table 1: Overview of CHP Technical Potential in Alabama

Business Type	50-500 kW		0.5 - 1 MW		1 - 5 MW		5 - 20 MW		> 20 MW		Total

¹⁰⁰ A detailed breakdown of Wyoming technical potential by application and size range is available in Appendix D, page D-101. For more information see: www.energy.gov/chp-installs, www.energy.gov/chp-projects, www.energy.gov/chp-contacts.

V. Conclusions

Overall, multiple factors point toward increasing levels of CHP market penetration in the United States in the future. Some of these include lower operating costs for CHP due to the abundance of low-cost natural gas, environmental regulations that recognize CHP's efficiency benefits, the increasing need for resiliency in the face of grid outages, availability and replicability of packaged CHP systems, favorable policies and incentives, and utility interest. CHP will continue to play an important role in meeting demands for distributed generation, particularly in applications with favorable electric and thermal loads.

The analysis in this report shows that there is significant technical potential for additional CHP capacity. There is about 141GW of traditional topping cycle CHP potential for on-site use distributed among the industrial (65GW) and commercial (76GW) sectors. The commercial sector has a higher potential because of the higher number of sites and the smaller base of existing installed CHP capacity. Due to the high thermal and electric loads found within industrial applications, many prime candidate sites have already chosen to install a CHP unit, however this analysis shows that many of these sites have the potential for further expansion of their CHP capacity.

In addition to the on-site CHP potential in the industrial and commercial sectors, the industrial sector has several application types that have significant potential to export electricity to the grid if they size CHP systems to the thermal load at their facility. The refining and chemical industries have the most such potential, and there is 81GW of total export capacity that could be installed.

The total WHP CHP technical potential is 7.6GW across all potential industries and waste heat streams at 1,105 candidate facilities. Petroleum refining, metals, and non-metallic minerals contain roughly 7GW (91%) of the entire technical potential. Unlike traditional CHP potential that is more spread out around the country, about one third of the WHP CHP technical potential is geographically located in just three states: Texas, Louisiana, and Indiana.

District energy technical potential represents a new area explored in this report compared to previous analyses on CHP technical potential. Downtown loops were divided into those with existing CHP systems with the potential for expansion and those without CHP installed. Overall, there is 10.6GW of CHP technical potential among 64 identified downtown or utility district energy loops in the U.S. This is technical potential only, and therefore does not take economics into account, however, all of the electricity generation from this CHP potential is assumed to be exported to the grid, which could impact the economic potential compared to facilities that could use the electricity on-site.

In **Figure V-1**, the amount of existing CHP is shown along with the amount of remaining CHP technical potential by application (except for district energy where the export CHP potential is shown). Export potential would increase the green portion of the bars significantly; however exporting electricity is often uneconomical. While there is still remaining CHP potential in large

industrial applications, it is the commercial applications that show the greatest amount of technical potential.

Figure V-1: Existing CHP Compared to CHP Technical Potential by Sector

U.S. DOE CHP Deployment Program, 2016.

In **Figure V-2**, the amount of existing CHP is shown on the state level, along with the remaining amount of technical potential in each state. The CHP technical potential in each bar includes the on-site industrial topping cycle CHP, commercial topping cycle CHP, WHP CHP, and district energy CHP.

Appendix A. Technical Potential Estimation Methodology

The technical potential is an estimation of market size constrained only by technological limits — the ability of CHP technologies to fit customer energy needs. CHP technical potential is calculated in terms of CHP electrical generation capacity that could be installed at existing industrial and commercial facilities based on the estimated electric and thermal needs of the site. The technical potential is useful in understanding the potential size and distribution of the CHP market in a target region. Identifying the technical market potential is a preliminary step in the assessment of the economically feasible market size and ultimate market penetration. This analysis focuses on sites with CHP technical potential of 50kW or higher.

Three different types of CHP markets were included in the evaluation of CHP technical potential for this study:

- Traditional Topping Cycle CHP (including cooling)
- Waste Heat to Power (WHP) CHP
- District Energy including CHP

General CHP Technical Potential Estimation Approach

The determination of technical market potential consists of the following elements:

- Identify target markets where CHP provides a reasonable fit to the electric and thermal needs of the user. Target applications are identified based on reviewing the electric and thermal energy consumption data for various building types and industrial facilities.
- Quantify the number and size distribution of target markets. Several data sources were used to identify the number of target candidate facilities in each target application that meet the electric and thermal load requirements for CHP.
- Estimate CHP potential in terms of MW electric capacity. CHP potential is derived based on the thermal and electric load for each site. Total CHP potential for each target market is then calculated by the amount of CHP potential in each size category.
- Subtract existing CHP from the identified sites to determine the remaining technical potential.

Technical Potential for Traditional Topping Cycle CHP

TRADITIONAL CHP TARGET MARKETS

There are a number of commercial buildings and industrial facilities that characteristically have sufficient and coincident thermal and electric loads for CHP. Most commercial and light industrial markets have low base thermal loads relative to the electric load, but have high thermal loads in the cooler months for heating. Such commercial buildings include hotels, hospitals, nursing homes, college campuses, correctional facilities, and light manufacturing. **Table A- 1** and **Table A- 2** display the target markets used for this study with an indicator of which market type each facility type fits under.

Table A- 1: Industrial CHP Target Markets

SIC	NAICS	Industrial Facility Type	Market Type
20	311	Food & Beverage	High Load Traditional
22	313	Textiles	High Load Traditional
24	321	Lumber and Wood	High Load Traditional
25	337	Furniture	High Load Traditional
26	322	Paper	High Load Traditional
27	323	Printing/Publishing	High Load Traditional
28	325	Chemicals	High Load Traditional
29	324	Petroleum Refining	High Load Traditional
30	326	Rubber/Miscellaneous Plastics	High Load Traditional
32	327	Stone/Clay/Glass	High Load Traditional
33	331	Primary Metals	High Load Traditional
34	332	Fabricated Metals	High Load Traditional
35	333	Machinery/Computer Equip.	High Load Traditional
37	336	Transportation Equip.	High Load Traditional
38	334	Instruments	High Load Traditional
39	339	Miscellaneous Manufacturing	High Load Traditional
49	486	Gas Processing	High Load Traditional

Table A- 2: Commercial CHP Target Markets

SIC	NAICS	Commercial Building Type	Market Type
43	491	Post Offices	Low Load Cooling
52	444	Big Box Retail	Low Load Cooling
4222	493	Refrigerated Warehouses	High Load Cooling
4581	488	Airports	Low Load Cooling
4952	221	Waste Water Treatment Plants	High Load Traditional
5411	445	Food Sales	Low Load Cooling
5812	722	Restaurants	Low Load Cooling
6512	531	Commercial Buildings	Low Load Cooling
6513	531	Multi-Family Buildings	High Load Cooling
7011	721	Hotels	High Load Cooling
7211	812	Laundries	Low Load Traditional
7374	518	Data Centers	High Load Cooling
7542	811	Carwashes	Low Load Traditional
7832	512	Movie Theaters	Low Load Cooling
7991	713	Health Clubs	Low Load Traditional
7997	713	Golf/Country Clubs	Low Load Traditional
8051	623	Nursing Homes	High Load Cooling
8062	622	Hospitals	High Load Cooling
8211	611	Schools	Low Load Cooling
8221	611	Colleges/Universities	High Load Cooling
8412	712	Museums	Low Load Cooling
9100	921	Government Facilities	Low Load Cooling
9223	922	Prisons	High Load Traditional
9711	928	Military	High Load Cooling

Traditional CHP Target Facilities Identification

Several commercial and industrial facility databases were used to identify the target market facilities in the country by sector and size range (electric demand) that meet the thermal and electric load requirements for CHP. The two primary sources used to identify potential targets for CHP were the Dun and Bradstreet (Hoover's) database and the Manufacturer's News (MNI) database. The Hoovers database contains information on the majority of businesses throughout the country, and can be sorted to provide a listing of industrial and commercial facilities in a specific region or application.¹⁰¹ For commercial office buildings and multi-family dwellings, data was extracted from the U.S. Census and Emporis database on the number of buildings in each state and the size of the buildings.

Electric and Thermal Loads for Traditional CHP Target Facility Types

ELECTRIC LOAD ESTIMATION

The electric requirements for each of the target facility types were estimated based on either electricity consumption factors applied to the number of employees at the site or another application-specific characteristic of the site. Some sources contained specific site information that could be used to estimate the facility electric load, such as, production capacity or equipment (for many industrial facilities), number of students, number of beds, or number of inmates (for commercial buildings). For sites containing no specific information, the number of employees working on-site was used as an indicator of site electric load. An average MWh per employee factor was then applied to site data, resulting in the average on-site electric requirements.

THERMAL LOAD ESTIMATION

Thermal load estimation is important to properly size the CHP system for high thermal utilization. This study assumes that CHP systems would be sized to meet the base thermal loads (heating and cooling) of each site, because sizing to the thermal load leads to the most efficient CHP system operation. In order to size the CHP system to meet the thermal demand of the facility, the project team applied a market-specific thermal factor to estimate the CHP system capacity that could meet the thermal needs of the facility.

The thermal factor is based on both the power-to-heat ratio (P/H) of the facility type as well as the P/H ratio of a typical CHP system by size range. The thermal factors indicate the ratio of electricity generation to thermal energy generation. A thermal factor of one would size a CHP system to match the electric load of the facility. A thermal factor less than one would result in a system capacity below the average electric load of the facility. A thermal factor greater than one would

¹⁰¹ The full list of sources used to compile the data for this study is: Association for Iron and Steel Plant Directory, Hoovers, Lockwood Post, Major Industrial Plant Database (MIPD), Manufacturer's News, Oil & Gas Journal, Portland Cement Directory, USGS Aluminum Data, American Hospital Association, Census of Federal Facilities, Emporis, Federal Aviation Administration Airports List, International District Energy Association, National Center for Education Statistics, the U.S. Census and the U.S. Military Base List.

result in a system sized to the thermal load, producing more electricity than what is required on-site. A number of industrial facilities have thermal factors greater than one, indicating the potential to export power to the grid for CHP systems sized to meet thermal loads.¹⁰²

Thermal factors vary by size range due to differences in CHP system P/H ratios. As CHP systems increase in size, their P/H ratios also tend to increase as electrical efficiency improves and heat available for recovery decreases. This analysis is based primarily on natural gas-fired reciprocating engines and combustion turbine systems, however for some market types like paper and wood products that tend to use waste fuels in a boiler/steam turbine system, lower P/H ratios were used¹⁰³.

Traditional CHP System Sizing

Using the estimated site electric loads and thermal factors, a potential CHP capacity was determined for each target facility type, which were then grouped into size bins based on the CHP system size that would best meet the site electric and thermal needs. The five size bins included in this study are:

- 50 – 500kW
- 500kW – 1MW
- 1 – 5MW
- 5 – 20MW
- >20MW

These size bins are used for characterization purposes, as well as the means for assigning appropriate CHP system characteristics for later economic potential analysis. There is no maximum size for CHP systems in the study.

Technical Potential for Waste Heat to Power (Bottoming-Cycle CHP)

Waste heat to power technologies produce power by capturing some form of waste heat, typically steam, and converting it into electricity. Unlike traditional topping cycle CHP, which produces power and useful thermal energy, WHP's sole purpose is to produce electricity using existing waste heat streams. While three primary categories¹⁰⁴ for waste heat to power exist, this report will only analyze bottoming-cycle CHP or WHP CHP. In a WHP CHP bottoming-cycle, fuel is

¹⁰² The P/H ratios for industrial markets were calculated based on [EIA's Manufacturing Energy Consumption Survey \(MECS\)](#) and for commercial markets based on [EIA's Commercial Building Energy Consumption Survey \(CBECS\)](#). This data was cross-checked and adjusted based on data from other sources like the California Energy Use Survey (CEUS) and the Major Industrial Plant Database (MIPD). A table showing the P/H ratios that were used for each business type is located in Appendix B.

¹⁰³ P/H ratios for natural gas-fired technologies ranged from 0.6 to 1.2 and P/H ratios for waste fuel technologies ranged from 0.1 to 0.6.

¹⁰⁴ The two classifications of WHP not discussed in this report are waste heat recovery from a mechanical drive and general waste heat recovery. These differ from bottoming cycle CHP in that a fuel is not combusted to create thermal energy. In waste heat recovery, the waste heat is generally a byproduct of a process (i.e. gas turbine, a kiln, or another industrial process).

combusted to provide thermal input to industrial process equipment like a kiln or furnace, and the heat rejected from the process is then captured and used for power production. Heat in a WHP CHP can be recovered from a furnace, oven, kiln, and other industrial processes¹⁰⁵ and converted to electricity using a thermodynamic process such as a Rankine cycle steam turbine.¹⁰⁶

There are approximately 75 known waste heat to power systems currently installed in the United States, totaling 469MW of capacity.¹⁰⁷ Existing systems are concentrated in the chemical, primary metals, and petroleum refining industries.

The determination of the WHP CHP technical potential includes the following process:

- Identify target markets with available waste heat flow and where WHP CHP provides a reasonable fit to the electric needs of the user. Target markets are identified based on reviewing the electric consumption and waste heat data for various building types and industrial markets.
- Quantify the number and size distribution of target markets. Several data sources were used to identify the number of target candidate facilities in each target market that meet the waste heat requirements for WHP CHP.
- Estimate WHP CHP potential in terms of MW electric capacity. WHP CHP potential is derived based on the waste heat quality and electric load for each site. Total WHP CHP potential for each target market is then calculated by the amount of WHP CHP potential in each size category.

WHP CHP TARGET MARKETS

WHP CHP systems require a constant and ample supply of waste heat, because WHP CHP systems will typically run for most hours of the year.¹⁰⁸ Heavy industrial processes such as cement production, advanced oil extraction and refining, or paper production will typically have the waste heat streams necessary to drive a WHP CHP system. Key commercial markets include colleges, and waste management. These markets will typically have waste heat temperatures high enough to make a WHP CHP system an economically viable option for on-site power generation. **Table A- 3** shows ideal applications for WHP CHP.

¹⁰⁵ Processes include calciners, kilns, flares, incinerators, ovens, reciprocating engines, regenerative oxidizers, thermal oxidizers, and exhaust from petroleum refining.

¹⁰⁶ Other thermodynamic processes, such as organic Rankine cycle (ORC) and Kalina cycles, can be used, particularly for lower temperature waste heat streams.

¹⁰⁷ DOE/ICF CHP Installation Database (U.S. installations as of December 31, 2014)

¹⁰⁸ For the purposes of this study, ICF assumes 8,000 hours/year.

Table A- 3: WHP CHP Target Markets

SIC	NAICS	Application Description
29	324	Total Petroleum and Coal Products
	324111	<i>Petroleum Refining</i>
	<i>Other 324</i>	<i>Other Petroleum and Coal</i>
33	331	Total Primary Metals
	331111	<i>Primary Metals - Iron and Steel</i>
	331511	<i>Primary Metals - Iron Foundries</i>
	<i>Other 331</i>	<i>Primary Metals – Other</i>
32	327	Total Non-Metallic Minerals
	3272	<i>Non-Metallic Minerals – Glass</i>
	327310	<i>Non-Metallic Minerals - Cement</i>
	327410	<i>Non-Metallic Minerals - Lime</i>
	<i>Other 327</i>	<i>Non-Metallic Minerals - Other</i>
13	211	Oil and Gas Extraction
28	325	Chemicals
12	212	Mining, except Oil and Gas
20	311	Food
26	322	Paper
35	333	Machinery
37	336	Transportation Equipment
24	321	Lumber and Wood
21	312	Beverage and Tobacco
27	323	Printing
38	334	Computer and Electronic Products
8221	611	Colleges/Universities
30	326	Rubber/Misc. Plastics
4222	493	Warehousing and Storage

WHP CHP DATA COLLECTION

ICF used data from a variety of sources to estimate the WHP CHP technical potential, including the EPA Greenhouse Gas Reporting Program (EPA GHGRP) database, Oil and Gas Journal, Portland Cement Association, and Association of Iron and Steel.

The technical potential analysis for WHP CHP sites was constrained to waste heat sources with a temperature of 450°F or higher. Power generation from waste heat has predominantly occurred with medium- to high-temperature waste heat sources (i.e., > 450°F) for commercially available technologies. There are several emerging technologies that utilize low-temperature waste heat streams that are in the demonstration stage in the U.S. and may become commercially available in the future.

WHP CHP System Sizing

Sizing a WHP CHP system to a facility follows a different process than sizing a conventional CHP system. The methodology to estimate the WHP CHP system size utilized the temperature of the stack gas emissions minus an assumed minimum temperature of 250°F. This difference was then

multiplied by the average specific heat for combustion of 0.26 BTU/lb. The result was the energy content of the stack gas emissions. **Table A- 4** displays the exhaust heat stack temperatures assumed for the various processes and equipment types. Each waste heat temperature has a Carnot theoretical electrical efficiency associated with converting the waste heat steam into electricity. In practice, however, the actual electrical efficiencies achieved by these systems are less than the Carnot efficiency.¹⁰⁹

The WHP CHP prime mover technology chosen for the site was tailored to each facility type. **Table A-5** displays the assumed prime mover selected by application. The project team selected an Organic Rankine Cycle (ORC) or a Steam Rankine Cycle (SRC), depending on the application in which the WHP system is installed. Rankine cycle technologies were chosen because of their widespread commercial availability and economic feasibility compared to other types of WHP CHP prime mover technologies. The selection by market will often depend on the quality of the waste heat (in terms of temperature). Commercially available ORC technologies using gaseous heat sources usually require a temperature of at least 450°F.¹¹⁰

Table A- 4: Stack Emissions Temperature by Equipment

Equipment	Temperature (°F)	Equipment	Temperature (°F)
GHGRP Equipment		Gas Refining	
Calciner, Kilns	700	Crude Distillation	316
Flare	1,200	Vacuum Distillation	421
Incinerator	1,400	Coking	800
Oven	700	Thermal Cracking	800
Reciprocating Engine	800	Visbreaking	800
Regenerative Oxidizer	1,200	Catalytic Cracking	1,148
Thermal Oxidizer	1,200	Catalytic Reforming	900
Cement Manufacturing (type of kiln)		Hydrocracking	800
Dry	840	Desulfurization	968
Dry/Precalciner	640	Alkylation	800
Dry/Preheater	640	Coke Production	1,000
Wet	640	Steam Methane Reforming	1,500

¹⁰⁹ For WHP systems using the Rankine cycle, the electrical efficiencies are generally 30-50% of the “theoretical” or Carnot efficiency for the technology-temperature pairing. For this study, Rankine cycle efficiencies were estimated to be 40% of the Carnot efficiency.

¹¹⁰ Hot exhaust gas from industrial processes will typically satisfy this criterion.

Table A- 5: WHP Prime Mover Technology by Facility Type

NAICS	NAICS Description	WHP Technology
211	Oil and Gas Extraction ¹¹¹	ORC
212	Mining, Except Oil and Gas	ORC
311	Food	SRC
312	Beverage and Tobacco	SRC
321	Wood	SRC
322	Paper	SRC
323	Printing	SRC
324	Petroleum and Coke Products	SRC
325	Chemical	SRC
327	Non-Metallic Minerals	SRC
331	Primary Metals	SRC
333	Machinery	SRC
336	Transportation Equipment	SRC
611	Colleges/Universities	SRC
326	Rubber/Misc. Plastics	SRC
493	Warehousing and Storage	ORC

Technical Potential for District Energy

A new market that is included in this study as a target market for CHP is district energy. District energy systems produce and deliver steam, hot water or chilled water through dedicated underground piping networks to heat or cool buildings in a given area. By combining individual user loads, district energy systems can deliver energy services in a more efficient, economic, and environmentally friendly manner. District energy systems also provide economies of scale for equipment management to optimize the use of fuels, power and resources¹¹². Typical settings ideal for district energy are downtown urban areas, college campuses, military bases, airports, or hospital campuses.

¹¹¹ The gas processing sizing methodology is the only market that used a noticeably different methodology than that of the GHGRP data. This data originated from the Oil and Gas Journal's gas processing database. In order to estimate the WHP technical potential, ICF used the daily gas processing rate (in MMcfd) and matched it to an existing site's characteristics that has WHP as a model to size a system.

¹¹² Energy and Environmental Analysis, Inc. and the International District Energy Association. "District Energy Services, Commercial Data Analysis for EIA's National Energy Modeling System." August 2007.

Figure A- 1: Diagram of a District Energy Loop

Source: International District Energy Association

Combined heat and power is particularly well-suited for integration into a district energy system. The high thermal loads exhibited by district energy systems are ideal for a CHP system's thermal outputs and provide a consistent thermal load that allows for high operating hours. The captured heat from the CHP unit can be used to create the steam and hot/chilled water necessary for the district energy system. Applying a CHP unit to a power plant and connecting it to a district energy loop will increase the efficiency of the power plant due to the capture and utilization of the waste heat.

Most district energy systems in the United States use steam as the medium to provide heating services. Hot water is also used for thermal energy distribution and can provide heat transmission over longer distances with less distribution heat loss. Cooling services are provided to users through the distribution of chilled water through closed loop networks. The majority of cooling capacity is provided by electrically driven centrifugal chillers, however, steam turbine-driven chillers and absorption chillers are used in a number of combined district heating and cooling systems. Cooling can also be provided on-site through the use of steam turbine and absorption chillers driven by steam supplied through district heating loops.¹¹³

CHP Sizing of District Energy Systems

For this study, a dataset of existing district energy systems compiled by the International District Energy Association (IDEA) was used to identify district energy loops operating in the U.S. that have CHP and those that do not.

The project team separated the systems out by the facility types that they served, therefore separating university, military bases, and other system types from "downtown/utility" systems.

¹¹³ Ibid.

Doing so reduced the risk of double counting the CHP potential in district energy with traditional CHP potential already identified. Downtown loops are also unique from other district energy markets because multiple legal entities are recipients of energy from the system. This creates a complex scenario for how to deal with the electricity generated by a CHP system. Most states limit the number of entities that can buy electricity from one provider before it is labeled as an electric utility. Because of this, the electricity produced by a CHP unit serving a district energy system is assumed to be exported back to the grid.

Since district energy systems provide thermal energy (in the form of steam, hot water, and/or chilled water) to satisfy the heating and cooling requirements of a group of buildings or a campus, there is not always an on-site electric load. In the analysis for traditional CHP and WHP, the CHP system size is limited so as not to exceed on-site electric demand, therefore avoiding the need to export power to the grid. However, in the case of district energy systems that serve multiple customers, all of the electricity generated by the system may need to be sold to the local utility due to regulatory requirements around the sale of electricity.

For this analysis, when sizing a CHP system to a district energy loop, the system is sized to the thermal load of the system with no limitations on the electric capacity, because all electricity is assumed to be exported to the grid. For systems that only had one thermal product (i.e. steam or hot water), the CHP system was sized to meet that thermal demand. If a site had multiple thermal requirements (i.e. chilled water and hot water), the CHP system was sized to meet the largest of the thermal loads. This ensures that the system satisfies both requirements throughout the year. This is a conservative method to avoid overestimation of CHP technical potential for district energy systems.

Appendix B. Power to Heat Ratios by Facility Type

NAICS	NAICS Description	P/H Ratio
311111	Dog and cat food manufacturing	0.451
311119	Other animal food manufacturing	0.547
311211	Flour milling	0.547
311212	Rice milling	0.511

Appendix D. Detailed Breakdowns of State CHP Technical Potential

Alabama

- Alabama has 2,777 MW of overall CHP capacity identified at 4,512 sites.
 - 1,382 MW of industrial on-site CHP potential, primarily in the chemicals, textiles, primary metals, paper and food sectors.
 - 1,143 MW of commercial on-site CHP potential, primarily in the government buildings, commercial buildings, colleges/universities, hospitals and schools sectors.
- Alabama has 251 MW of WHP CHP potential identified at 35 sites in the mining, oil and gas extraction, paper, refining, stone/clay/glass and primary metals sectors.
- There is no CHP district energy potential identified in Alabama.

Sub-Table 1.2: District Energy CHP Technical Potential (Subset of Total CHP Technical Potential)

There is no known CHP technical potential at existing district energy loops in Alabama.

Alaska

- Alaska has 408 MW of overall CHP capacity identified at 632 sites.
 - 144 MW of industrial on-site CHP potential, primarily in the petroleum refining, chemicals, gas processing, food, lumber and wood, and chemicals sectors.
 - 191 MW of commercial on-site CHP potential, primarily in the military, colleges/universities, commercial (office) buildings, government buildings and hospitals sectors.
- Alaska has 73 MW of WHP CHP potential identified at 7 sites in the mining, oil and gas extraction, and petroleum refining sectors.
- There is no CHP district energy potential identified in Alaska.

There is no known CHP technical potential at existing district energy loops in Alaska.

Arizona

- Arizona has 2,422 MW of overall CHP capacity identified at 5,703 sites.
 - 638 MW of industrial on-site CHP potential, primarily in the primary metals, chemicals, food, paper and transportation equipment sectors.
 - 1,654 MW of commercial on-site CHP potential, primarily in the schools, commercial (office) buildings, colleges/universities, multifamily buildings and hotels sectors.
- Arizona has 28 MW of WHP CHP potential identified at 4 sites in the stone/clay/glass sector.
- Arizona has 102 MW of CHP potential identified at 3 district energy sites.

Arkansas

- Arkansas has 1,795 MW of overall CHP capacity identified at 2,664 sites.
 - 965 MW of industrial on-site CHP potential, primarily in the chemicals, paper, food, lumber and wood, and rubber/plastics sectors.
 - 668 MW of commercial on-site CHP potential, primarily in the colleges and universities, commercial (office) buildings, hospitals, schools, and retail sectors.
- Arkansas has 162 MW of WHP CHP potential identified at 11 sites in the oil and gas extraction, paper, refining, stone/clay/glass, and primary metals sectors.
- There is no CHP district energy potential identified in Arkansas.

Colorado

- Colorado has 1,719 MW of overall CHP capacity identified at 4,544 sites.
 - 558 MW of industrial on-site CHP potential primarily in the food, chemicals, paper, refining, and primary metals sectors.
 - 1,024 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges/universities, hotels, hospitals, and multifamily buildings sectors.
- Colorado has 84 MW of WHP CHP potential identified at 32 sites in the oil and gas extraction, refining, stone/clay/glass, and primary metals sectors.
- Colorado has 53 MW of CHP potential identified at 1 district energy site.

Connecticut

- Connecticut has 1,323 MW of overall CHP capacity identified at 3,443 sites.
 - 415 MW of industrial on-site CHP potential primarily in the chemicals, transportation equipment, paper, food, and rubber/plastics sectors.
 - 799 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges/universities, government buildings, multifamily buildings and hospitals sectors.
- Connecticut has 0.1 MW of WHP CHP potential identified at 1 site in the chemicals sector.
- Connecticut has 109 MW of CHP potential identified at 3 district energy sites.

District of Columbia

- The District of Columbia has 908 MW of overall CHP capacity identified at 757 sites.
 - 4 MW of industrial on-site CHP potential primarily in the printing, refining and instruments sectors.
 - 757 MW of commercial on-site CHP potential, primarily in the government buildings, colleges and universities, multifamily buildings, airports, and hotels sectors.
- There is no WHP CHP potential identified in the District of Columbia.
- The District of Columbia has 146 MW of CHP potential identified at 1 district energy site.

Delaware

- Delaware has 747 MW of overall CHP capacity identified at 832 sites.
 - 481 MW of industrial on-site CHP potential primarily in the chemicals, refining, food, transportation equipment, and paper sectors.
 - 207 MW of commercial on-site CHP potential, primarily in the colleges/universities, commercial (office) buildings, schools, hospitals, and hotels sectors.
- Delaware has 60 MW of WHP CHP potential identified at 2 sites in the refining and primary metals sectors.
- There is no CHP district energy potential identified in Delaware.

Georgia

- Georgia has 5,110 MW of overall CHP capacity identified at 9,374 sites.
 - 2,725 MW of industrial on-site CHP potential primarily in the chemicals, textiles, food, paper, and lumber and wood sectors.
 - 2,371 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, schools, hospitals and military sectors.
- Georgia has 14 MW of WHP CHP potential identified at 7 sites in the paper, chemicals, and stone/clay/glass sectors.
- There is no CHP district energy potential identified in Georgia.

There is no known CHP technical potential at existing district energy loops in Georgia.

Hawaii

- Hawaii has 563 MW of overall CHP capacity identified at 1,292 sites.
 - 69 MW of industrial on-site CHP potential primarily in the food, chemicals, refining, primary metals, and lumber and wood sectors.
 - 486 MW of commercial on-site CHP potential, primarily in the schools, hotels, colleges and universities, commercial (office) buildings, and multifamily buildings sectors.
- Hawaii has 7 MW of WHP CHP potential identified at 2 sites in the petroleum refining sector.
- There is no CHP district energy potential identified in Hawaii.

Sub-Table 1.2: District Energy CHP Technical Potential (Subset of Total CHP Technical Potential)

There is no known CHP technical potential at existing district energy loops in Idaho.

Illinois

- Illinois has 7,464 MW of overall CHP capacity identified at 13,717 sites.
 - 3,733 MW of industrial on-site CHP potential primarily in the chemicals, food, refining, primary metals, and paper sectors.
 - 3,075 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, multifamily buildings, hospitals, and retail sectors.
- Illinois has 353 MW of WHP CHP potential identified at 25 sites in the oil and gas extraction, chemicals, refining, stone/clay/glass, and primary metals sectors.
- Illinois has 303 MW of CHP potential identified at 2 district energy sites.

Indiana

- Indiana has 4,610 MW of overall CHP capacity identified at 7,273 sites.
 - 2,151 MW of industrial on-site CHP potential primarily in the chemicals, primary metals, food, transportation equipment, and paper sectors.
 - 1,521 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, college and universities, hospitals, retail, and schools sectors.
- Indiana has 473 MW of WHP CHP potential identified at 27 sites in the chemicals, petroleum refining, stone/clay/glass, and primary metals sectors.
- Indiana has 465 MW of CHP potential identified at 1 district energy site.

Iowa

- Iowa has 1,993 MW of overall CHP capacity identified at 3,723 sites.
 - 1,235 MW of industrial on-site CHP potential primarily in the food, chemicals, rubber and plastics, paper, and primary metals sectors.
 - 670 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, hotels, and food stores sectors.
- Iowa has 88 MW of WHP CHP potential identified at 16 sites in the chemicals, stone/clay/glass, primary metals and machinery sectors.
- There is no CHP district energy potential identified in Iowa.

There is no known CHP technical potential at existing district energy loops in Iowa.

Kansas

- Kansas has 1,909 MW of overall CHP capacity identified at 3,158 sites.
 - 1,039 MW of industrial on-site CHP potential, primarily in the primary metals, refining, chemicals, food, and transportation equipment sectors.
 - 749 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges/universities, hospitals and military and schools sectors.
- Kansas has 122 MW of WHP CHP potential identified at 21 sites in the refining, stone/clay/glass, chemicals, and oil/gas extraction sectors.
- There is no CHP district energy potential identified in Kansas.

There is no known CHP technical potential at existing district energy loops in Kansas.

Kentucky

- Kentucky has 2,721 MW of overall CHP capacity identified at 4,030 sites.
 - 1,598 MW of industrial on-site CHP potential primarily in the chemicals, food, petroleum refining, paper, and primary metals sectors.
 - 911 MW of commercial on-site CHP potential, primarily in the military, retail, commercial buildings, universities, and hospitals sectors.
- Kentucky has 211 MW of WHP CHP potential identified at 18 sites in the chemical, stone/clay/glass, oil and gas extraction, paper, printing, and primary metals sectors.
- There is no CHP district energy potential identified in Kentucky.

Sub-Table 1.2: District Energy CHP Technical Potential (Subset of Total CHP Technical Potential)

There is no known CHP technical potential at existing district energy loops in Kentucky.

Louisiana

- Louisiana has 4,946 MW of overall CHP capacity identified at 4,437 sites.
 - 3,011 MW of industrial on-site CHP potential primarily in the chemicals, food, petroleum refining, paper, and gas processing sectors.
 - 1,109 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, schools, hospitals, and hotels sectors.
- Louisiana has 782 MW of WHP CHP potential identified at 93 sites, primarily in the oil and gas extraction, petroleum refining and primary metals sectors.
- Louisiana has 43 MW of identified at 1 district energy site.

Maine

- Maine has 494 MW of overall CHP capacity identified at 1,385 sites.
 - 223 MW of industrial on-site CHP potential primarily in the paper, chemicals, lumber and wood, food, and textiles sectors.
 - 266 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, hotels, and food stores sectors.
- Maine has 4 MW of WHP CHP potential identified at 3 sites in the paper and stone/clay/glass sectors.
- There is no CHP district energy potential identified in Maine.

Massachusetts

- Massachusetts has 3,434 MW of overall CHP capacity identified at 6,659 sites.
 - 777 MW of industrial on-site CHP potential primarily in the chemicals, paper, food, rubber and plastics, and textiles sectors.
 - 2,249 MW of commercial on-site CHP potential primarily in the hospitals, colleges and universities, commercial (office) buildings, multifamily buildings and government sectors.
- Massachusetts has 3 MW of WHP CHP potential identified at 3 sites in the stone/clay/glass and instruments sectors.
- Massachusetts has 406 MW of CHP potential identified at 2 district energy sites.

Michigan

- Michigan has 4,987 MW of overall CHP capacity identified at 10,370 sites.
 - 2,170 MW of industrial on-site CHP potential primarily in the transportation equipment, chemicals, primary metals, paper, and food sectors.
 - 1,967 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, retail, and multifamily buildings sectors.
- Michigan has 154 MW of WHP CHP potential identified at 36 sites primarily in the oil and gas extraction, refining, stone/clay/glass, and primary metals sectors.
- Michigan has 696 MW of CHP potential identified at 2 district energy sites.

Mississippi

- Mississippi has 1,833 MW of overall CHP capacity identified at 2,629 sites.
 - 966 MW of industrial on-site CHP potential primarily in the refining, chemicals, paper, lumber and wood, and food sectors.
 - 691 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, schools, and hotels sectors.
- Mississippi has 176 MW of WHP CHP potential identified at 9 sites, primarily in the oil and gas extraction, refining and primary metals sectors.
- There is no CHP district energy potential identified in Mississippi.

Sub-Table 1.2: District Energy CHP Technical Potential (Subset of Total CHP Technical Potential)

There is no known CHP technical potential at existing district energy loops in Mississippi.

Missouri

- Missouri has 3,290 MW of overall CHP capacity identified at 6,384 sites.
 - 1,276 MW of industrial on-site CHP potential primarily in the food, chemicals, paper, transportation equipment, and primary metals sectors.
 - 1,521 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, hotels, and retail sectors.
- Missouri has 85 MW of WHP CHP potential identified at 15 sites, primarily in the stone/clay/glass and chemicals sectors.
- Missouri has 408 MW of CHP potential identified at 2 district energy sites.

Montana

- Montana has 377 MW of overall CHP capacity identified at 942 sites.
 - 140 MW of industrial on-site CHP potential primarily in the refining, lumber and wood, primary metals, food, and chemicals sectors.
 - 179 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, hotels, and retail sectors.
- Montana has 58 MW of WHP CHP potential identified at 7 sites in the refining, food, and stone/clay/glass sectors.
- There is no CHP district energy potential identified in Montana.

There is no known CHP technical potential at existing district energy loops in Montana.

Nebraska

- Nebraska has 984 MW of overall CHP capacity identified at 2,067 sites.
 - 487 MW of industrial on-site CHP potential primarily in the food, chemicals, primary metals, paper, and textiles sectors.
 - 458 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, data centers, and government buildings sectors.
- Nebraska has 39 MW of WHP CHP potential identified at 9 sites in the food, refining, stone/clay/glass and primary metals sectors.
- There is no CHP district energy potential identified in Nebraska.

New Hampshire

- New Hampshire has 447 MW of overall CHP capacity identified at 1,363 sites.
 - 170 MW of industrial on-site CHP potential primarily in the chemicals, paper, textiles, food, and lumber and wood sectors.
 - 277 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, hotels, and food stores sectors.
- There is no WHP CHP potential identified in New Hampshire.
- There is no CHP district energy potential identified in New Hampshire.

There is no WHP CHP potential identified in New Hampshire.

Sub-Table 1.2: District Energy CHP Technical Potential (Subset of Total CHP Technical Potential)

There is no known CHP technical potential at existing district energy loops in New Hampshire.

New Jersey

- New Jersey has 3,796 MW of overall CHP capacity identified at 8,649 sites.
 - 1,456 MW of industrial on-site CHP potential primarily in the chemicals, food, paper, refining, and rubber/plastics sectors.
 - 2,199 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, multifamily buildings, government buildings, and hospitals sectors.
- New Jersey has 106 MW of WHP CHP potential identified at 10 sites in the refining, stone/clay/glass, and primary metals sectors.
- New Jersey has 35 MW of CHP potential identified at 2 district energy sites.

Sub-Table 1.2: District Energy CHP Technical Potential (Subset of Total CHP Technical Potential)

There is no known CHP technical potential at existing district energy loops in New Mexico.

New York

- New York has 10,818 MW of overall CHP capacity identified at 16,901 sites.
 - 1,877 MW of industrial on-site CHP potential primarily in the chemicals, food, paper, primary metals, and textiles.
 - 4,981 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, multifamily buildings, government buildings, and hospitals sectors.
- New York has 50 MW of WHP CHP potential identified at 13 sites in the food, chemicals, stone/clay/glass, and primary metals sectors.
- New York has 3,910 MW of CHP potential identified at 4 district energy sites.

North Carolina

- North Carolina has 4,352 MW of overall CHP capacity identified at 8,437 sites.
 - 2,339 MW of industrial on-site CHP potential primarily in the textiles, chemicals, paper, lumber and wood, and food sectors.
 - 1,931 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, schools, and government buildings sectors.
- North Carolina has 82 MW of WHP CHP potential identified at 14 sites primarily in the stone/clay/glass and primary metals sectors.
- There is no CHP district energy potential identified in North Carolina.

Sub-Table 2: District Energy CHP Technical Potential (Subset of Total CHP Technical Potential)

There is no known CHP technical potential at existing district energy loops in North Dakota.

Ohio

- Ohio has 7,288 MW of overall CHP capacity identified at 13,194 sites.
 - 3,981 MW of industrial on-site CHP potential primarily in the chemicals, paper, primary metals, food, and refining sectors.
 - 2,717 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, government buildings, and retail sectors.
- Ohio has 307 MW of WHP CHP potential identified at 38 sites primarily in the refining, stone/clay/glass, and primary metals sectors.
- Ohio has 283 MW of CHP potential identified at 4 district energy sites.

Oklahoma

- Oklahoma has 1,916 MW of overall CHP capacity identified at 3,397 sites.
 - 790 MW of industrial on-site CHP potential primarily in the refining, chemicals, food, primary metals, and rubber/plastics sectors.
 - 851 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, schools, and military sectors.
- Oklahoma has 165 MW of WHP CHP potential identified at 70 sites in the oil and gas extraction, paper, refining, stone/clay/glass, and primary metals sectors.
- Oklahoma has 111 MW of CHP potential identified at 2 district energy sites.

Oregon

- Oregon has 1,342 MW of overall CHP capacity identified at 3,466 sites.
 - 646 MW of industrial on-site CHP potential primarily in the lumber and wood, food, chemicals, paper, and primary metals sectors.
 - 662 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, government buildings, and multifamily buildings sectors.
- Oregon has 29 MW of WHP CHP potential identified at 5 sites in the stone/clay/glass, primary metals, and instruments sectors.
- Oregon has 5 MW of CHP potential identified at 1 district energy site.

Pennsylvania

- Pennsylvania has 7,759 MW of overall CHP capacity identified at 12,708 sites.
 - 3,620 MW of industrial on-site CHP potential primarily in the chemicals, primary metals, paper, refining, and food sectors.
 - 3,003 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges and universities, hospitals, government buildings, and retail sectors.
- Pennsylvania has 402 MW of WHP CHP potential identified at 52 sites primarily in the refining, stone/clay/glass, and primary metals sectors.
- Pennsylvania has 734 MW of CHP potential identified at 3 district energy sites.

Rhode Island

- Rhode Island has 616 MW of overall CHP capacity identified at 1,114 sites.
 - 225 MW of industrial on-site CHP potential, primarily in the paper, chemicals, textiles, rubber/plastics and food sectors.
 - 391 MW of commercial on-site CHP potential, primarily in the hospitals, commercial (office) buildings, colleges/universities, multifamily buildings and government buildings sectors.
- Rhode Island has 10 kW of WHP CHP potential identified at 1 rubber/plastics site.
- There is no CHP district energy potential identified in Rhode Island.

Sub-Table 1.2: District Energy CHP Technical Potential (Subset of Total CHP Technical Potential)

There is no known CHP technical potential at existing district energy loops in Rhode Island.

South Carolina

- South Carolina has 3,063 MW of overall CHP capacity identified at 4,273 sites.
 - 1,656 MW of industrial on-site CHP potential, primarily in the chemicals, paper, textiles, rubber/plastics and lumber and wood sectors.
 - 1,251 MW of commercial on-site CHP potential, primarily in the military, commercial (office) buildings, schools, colleges/universities and government buildings.
- South Carolina has 156 MW of WHP CHP potential identified at 12 sites in the lumber and wood, paper, stone/clay/glass and primary metals sectors.
- There is no CHP district energy potential identified in South Carolina.

Texas

- Texas has 14,062 MW of overall CHP capacity identified at 20,855 sites.
 - 5,216 MW of industrial on-site CHP potential, primarily in the chemicals, refining, food, primary metals and paper sectors.
 - 7,027 MW of commercial on-site CHP potential, primarily in the schools, colleges/universities, commercial (office) buildings, hospitals and multifamily sectors.
- Texas has 1,432 MW of WHP CHP potential identified at 244 sites in the refining, stone/clay/glass, oil and gas extraction and primary metals sectors.
- Texas has 387 MW of CHP potential identified at 7 district energy sites.

Utah

- Utah has 1,119 MW of overall CHP capacity identified at 2,676 sites.
 - 440 MW of industrial on-site CHP potential, primarily in the chemicals, food, refining, paper and primary metals sectors.
 - 618 MW of commercial on-site CHP potential, primarily in the colleges/universities, commercial (office) buildings, hospitals, government buildings, and hotels sectors.
- Utah has 61 MW of WHP CHP potential identified at 21 sites in the refining, stone/clay/glass, oil and gas extraction and primary metals sectors.
- There is no CHP district energy potential identified in Utah.

There is no known CHP technical potential at existing district energy loops in Utah.

Vermont

- Vermont has 228 MW of overall CHP capacity identified at 657 sites.
 - 112 MW of industrial on-site CHP potential, primarily in the paper, food, lumber and wood, chemicals, and textiles sectors.
 - 116 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges/universities, hotels, hospitals, and government buildings sectors.
- There is no waste heat to power CHP potential identified in Vermont.
- There is no CHP district energy potential identified in Vermont.

Virginia

- Virginia has 4,308 MW of overall CHP capacity identified at 7,291 sites.
 - 1,703 MW of industrial on-site CHP potential, primarily in the chemicals, paper, textiles, food, and lumber and wood sectors.
 - 2,540 MW of commercial on-site CHP potential, primarily in the military, commercial (office) buildings, colleges/universities, government buildings and hospitals sectors.
- Virginia has 65 MW of WHP CHP potential identified at 11 sites in the beverages and tobacco, chemicals, refining, stone/clay/glass and primary metals sectors.
- There is no CHP district energy potential identified in Virginia.

West Virginia

- West Virginia has 929 MW of overall CHP capacity identified at 1,630 sites.
 - 427 MW of industrial on-site CHP potential, primarily in the chemicals, primary metals, lumber and wood, paper, and refining sectors.
 - 354 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges/universities, hospitals, government buildings and hotels sectors.
- West Virginia has 148 MW of WHP CHP potential identified at 14 sites in the mining, oil and gas extraction, chemicals, refining, stone/clay/glass and primary metals sectors.
- There is no CHP district energy potential identified in West Virginia.

There is no known CHP technical potential at existing district energy loops in West Virginia.

Wisconsin

- Wisconsin has 3,474 MW of overall CHP capacity identified at 7,008 sites.
 - 1,783 MW of industrial on-site CHP potential, primarily in the paper, chemicals, food, lumber and wood, and rubber/plastics sectors.
 - 1,346 MW of commercial on-site CHP potential, primarily in the commercial (office) buildings, colleges/universities, government buildings, hospitals, and hotels sectors.
- Wisconsin has 57 MW of WHP CHP potential identified at 15 sites in the food, chemicals, refining, stone/clay/glass, primary metals and machinery sectors.
- Wisconsin has 287 MW of CHP potential identified at 2 district energy sites.
