WWW.Siemens.com

#### Introduction

- In parallel with the generation expansion plan Siemens PTI evaluated PREPA's transmission system and determined the convenience of its separation into 8 electrical islands called MiniGrids for short, considering the geography of the system and the expected time to repair for the various overhead lines.
- The concept is that following (or even in preparation for) a major event the system can be segregated into autonomous electrical islands that can operate separately from each other for extended periods of time including months.
- As presented earlier, the expansion plan is being designed so that there will be local resources to the MiniGrids and next we will present how this resources achieve balance with Critical, Priority and the total load. Also we will provide the identified investments necessary to consolidate the MiniGrids.
- Supplementary to the MiniGrids, microgrids as proposed for areas where there is difficulty of access and it would be impractical to harden the system to integrate them to the MiniGrid.

# **Eight MiniGrids – Ten Areas**

Red lines - Under 10 days with a target of few hours or ride through the storm

Yellow - Under 30 days after being hardened in accordance with new codes and standards, with a target of under 10 days

Green - Due to geography, could take over a month to repair after a major event.

Blue - 230 kV Long lines, Long recovery time, Not used for determining Minigrid boundaries due to inter-Minigrid in natural

Ten Areas considering that Ponce Minigrid is consist of Ponce East and Ponce West, and Bayamon and San Juan are one MiniGrid

## **MiniGrids – Loads Category**

# SIEMENS

- Critical Loads: these loads should either ride through the storm or must be available shortly after. They are crucial for the restauration effort, Including hospitals, airports, shelters and town center, police/fire stations, storm water pumps, critical water supply/treatment AAA facilities and certain communication facilities.
- Priority Loads: these loads are necessary to restore normalcy to localities and include shopping centers and commercial establishments, gas stations, industries, higher density residential areas. These loads must be reconnected shortly after the Critical Loads. Overhead lines may be inspected and repaired; no more than 10 days for the full connection.
- Balance Loads: these are the rest of the loads within the minigrid and the objective is to restore them also within 10 days of the event, but more overhead lines may be involved and 100% restauration may exceed 10 days.

# **MiniGrids – Microgrids Loads**

#### The load can be located in the MiniGrid or Microgrid:

• 16 % of the critical loads and 5% of the priority loads are located in the microgrids that require similar restoration time

# **MiniGrids Design**

The Design of the MiniGrids (and microgrids) consist of two overarching activities:

#### Local Generation Resource Selection:

- The critical loads must be able to be served by thermal resources only; full coverage right after the event.
- Priority loads to be served by a combination of thermal resources and PV + Storage.
- Balance of loads to be served by a combination of thermal resources and PV + Storage, and on grid isolated mode some level of load shed is accepted.
- Microgrid loads ideally should be covered by reciprocating engines assigned by the LTCE to the region. PV + Storage can complement.

#### Transmission / Distribution Design:

- Hardening / new underground facilities to create a MiniGrid backbone to which the generation is connected and loads are served from.
- Building underground facilities for interconnection of critical loads.
- New underground reliable facilities for the Interconnection of MiniGrids and faster consolidation.
- Extension of the MiniGrid backbone to areas of high reliability and resiliency.
- Hardening of the existing infrastructure or replacing aging infrastructure for MiniGrid as complementary to the above.

# **MiniGrids Design: 115 kV Transmission**

147 projects at 115 kV level analyzed for MiniGrids in the IRP context under the different categories and encompasses activities ranging from reconstruction to new lines as highlighted below.

- 70 out of the 147 projects are associated with MiniGrid Main Backbone
- One of the most important investments are those associated with new transmission lines / underground cables, which are presented here by area and technical justification.
- Most of them are associated with forming the MiniGrid main backbone

# MiniGrids Design: Transmission 115 kV

Overview of the key 115 kV projects designed to support the backbone of the MiniGrids or create interconnections between MiniGrid for fasted integration.

SIEMENS

Also provides a high level view of the spatial distribution of resources

# MiniGrids Design: 38 kV Transmission

 330 projects at 38 kV level analyzed for MiniGrids in the IRP context under different categories and encompasses activities ranging from reconstruction to new lines as highlighted below.

SIEMENS

Ingenuity for life

## MiniGrids Design: 38 kV Transmission

- 240 out of the 330 projects are associated with the Interconnection of Critical Loads
- Important investments are those associated with new transmission lines / underground cables, more than 120 new projects
- 107 of them are associated with the Interconnection of Critical Loads
- The rest are associated with Minigrid Backbone Extensions, Interconnection of MiniGrids, or Existing Infrastructure Hardening for Reliability – MG
- New projects will be presented in the following MiniGrids section

# **MiniGrids Design: 115 kV Transmission Investment**

• 115 kV MiniGrid Transmission Investment By Project Type

# **MiniGrids: Load Flow Analysis**

#### Summary

- The purpose of MiniGrid load flow analysis is to assess the reliability of the PREPA's transmission system operated under MiniGrid (isolated) mode following a major event.
- Since the destruction of transmission facilities already causing grid separations, we mainly focus on the precontingency flows and bus voltages.
- S4S2B with 2019 Night Peak load condition was analyzed.
- Two stages of system operations:
  - MiniGrid with microgrids connected, as could be the situation a few weeks after the major event
  - MiniGrid with all microgrids disconnected simulating the system in further destructive scenario or few days / weeks after the event

#### Observation

- No thermal or voltage violations were reported before contingency based on planning criteria under emergency
- In line with the results discussed in the Integrated Steady State Analysis
- The discussion on Integrated system, Weakened system, and Existing system will be presented in the Transmission Steady State Analysis section.

# Supply – Demand Balance: Arecibo MiniGrid

#### Resources

- The Arecibo MiniGrid under S4S2B is projected by 2023 to have 82 MW of thermal, 160 MW of Storage and 120 MW of PV (utility & customer owned)
- Note one Cambalache unit to retire in 2023 and the other unit must stay on throughout the planning period

#### **Observations**

- The local thermal resources cover the critical load (red band) for all years
- From 2021, capacity from all available resources cover the entire local load (red, yellow, and blue)
- Energy is not fully covered, indicating some level of load shedding could occur

# Supply – Demand Balance: Caguas MiniGrid

#### Resources

 The Caguas area under S4S2B is projected by 2024 to have 92.8 MW of thermal (4 new peakers), 300 MW of Storage and 520 MW of PV (utility & customer owned)

#### **Observations**

- By 2021 the local thermal resources cover the critical load
- From 2021, capacity from all available resources cover the entire local load
- Energy is not fully covered until 2028, indicating some level of load shedding could occur

# Supply – Demand Balance: Cayey MiniGrid

——Thermal Max Energy (GWh)

Total Energy thermal + PV

#### Resources

 The Cayey area under S4S2B is projected by 2022 to have 46.4 MW of thermal (2 new peakers), 160 MW of Storage and 120 MW of PV (utility & customer owned)

#### **Observations**

- By 2021 the local thermal resources cover the critical load (red band)
- From 2021, capacity from all available resources cover the entire local load
- Energy is not fully covered until 2023, indicating some level of load shedding could occur during the first couple years

Priority Load

Critical Load

# **MiniGrid VoLL Analysis**

#### Introduction

- Assess the economic impact of not advancing the proposed transmission investments
- Value of Lost Load (VoLL) was calculated under MiniGrid operations following a major event
- MiniGrids were separated into individual load pockets after multiple line outages assuming no MiniGrids transmission investment

#### Assumptions

- Level 1: transmission lines that are assumed to be out immediately after a major event
- Level 2: transmission lines that can be brought back in service one week after the event
- 2019 Night Peak load and 2025 S4S2B generation plan from LTCE
- Average load factor: 75% of the peak load
- Cost of unserved load: Critical Load \$32,000/MWh, Priority Load \$10,000/MWh, Balance Load \$2,000/MWh

#### Methodology

- Apply transmission outages to convert the Base Case to MiniGrids
- Apply Level 1 outages for the MiniGrid and identify the individual load pockets
- Apply Level 2 changes (put lines back into service) and identify the new load pockets after Level 2 changes
- Analyze load to generation balance for each individual load pocket and calculate the Load Not Served, the Energy Not Served, the Cost of Energy Not Served, broken down by the Critical, Priority, and Balance load

#### Conclusion

 The total VoLL for any severe event that caused transmission lines out for a few weeks would be more than enough to justify the total cost of the proposed MiniGrid transmission investment

# Supply – Demand Balance: Carolina MiniGrid

#### Resources

 The Carolina Area under S4S2B by 2023 is projected to have 92.8 MW of thermal (4 new peakers), 260 MW of Storage and 440 MW of PV (utility & customer owned)

#### **Observations**

- By 2021 the local thermal resources cover the critical load
- From 2022, capacity from all available resources cover the entire local load
- Energy is not fully covered until 2026, indicating some level of load shedding could occur

# Transmission Investment – Carolina MiniGrid

**CAROLINA REGION** 

#### **Transmission Lines**

- 230 kV Lines

# Supply – Demand Balance: Mayaguez North MG

#### Resources

 The Mayaguez North Area under S4S2B by 2022 is projected to have 92.8 MW of thermal (4 new peakers), 160 MW of Storage and 225 MW of PV (utility & customer owned)

#### **Observations**

- By 2021 the local thermal resources cover the critical load (red band)
- From 2021, capacity from all available resources cover the entire local load
- Energy is not fully covered until 2022, indicating some level of load shedding could occur during the first couple years

# Supply – Demand Balance: Mayaguez South MG

# Energy Coverage GWh

#### Resources

 The Mayaguez South Area under S4S2B is projected to have resource from thermal GT, 200 MW until 2023, then reduce to 100 starting 2030

SIEMENS

Ingenuity for life

#### **Observations**

- Local thermal resources cover the critical load (red band) for all years
- Energy is fully covered throughout, except for a slight shortage in 2030 to 2031

#### **Transmission Investment – Mayaguez North and South MG**

# Supply – Demand Balance: San Juan MG-Bayamon

#### Resources

 Bayamon area under S4S2B by 2025 is projected to have a new 305 MW of thermal (no new peaker and including a new CCGT at Palo Seco), 120 MW of Storage and 540 MW of PV (utility scale and customer owned)

#### **Observations**

- Local thermal resources cover the critical load for all years
- The load, by energy, is expected to be fully covered throughout, even considering the retirements

# Transmission Investment – San Juan MG-Bayamon

# **SIEMENS**

# Supply – Demand Balance: San Juan MG-San Juan

#### Resources

 San Juan area under S4S2B by 2024 is projected to have 400 MW of thermal (no new peaker), 120 MW of Storage and 60 MW of PV (utility scale)

SIEMENS

Ingenuity for life

#### **Observations**

- The LTCE retired all the steam generation in SJ and SJ 6 in 2024, and install the new CCGT starting 2020, and retire one unit in 2035
- Local thermal resources cover the critical load for all years
- Capacity from all available local resources cover most of the load
- Energy is calculated to be almost fully covered, considering resources from Bayamon area in the same MiniGrid can be used

## Supply – Demand Balance: Ponce MiniGrid-East

#### Resources

 Ponce East area under S4S2B by 2026 is projected to have 46.4 MW of thermal (2 new peakers) after the retirement of Aguirre CC in 2025, 0 MW of Storage and 30 MW of PV (customer owned)

#### **Observations**

- The LTCE retired all the thermal generation in Ponce East and install only new peaker units in 2026 and 2028
- Local thermal resources cover the critical load for all years
- Energy is calculated to be fully covered, considering resources from Ponce West area in the same MiniGrid can be used

## Supply – Demand Balance: Ponce MiniGrid-West

#### Resources

 Ponce West area under S4S2B by 2025 is projected to have 302 MW of Costa Sur CC thermal generation (no new peaker), 0 MW of Storage and 12 MW of PV (customer owned)

#### **Observations**

- The LTCE retired all the thermal generation in Ponce West by 2024 and install a new CC unit in 2025
- Considering resources from Ponce East area in the same MiniGrid:
  - All critical loads in Ponce MiniGrid are fully covered by thermal resources
  - Energy is fully covered in Ponce MiniGrid

#### **Transmission Investment –** *Ponce MiniGrid*

# Transmission Steady State Analysis

Restricted

WWW.Siemens.com

#### **Transmission Steady State Analysis**

#### Introduction

- Identify constraints, reliability issues, and critical contingencies based on an integrated system
- Considering higher likelihood of implementation, a total of 10 power flow cases were assessed
- Generation portfolios from the LTCE plans
- Additional cases were analyzed based on similarity of resources
- Considered both Day and Night Peak, 2025 and 2028

|      | S1S2B | S4S2B       | ESM         | S3S2B    | S5S1B    |  |
|------|-------|-------------|-------------|----------|----------|--|
| 2025 | Night | Day & Night | Day & Night | Analyzed | Analyzed |  |
| 2028 | Night | Day & Night | Day & Night | Analyzed | Analyzed |  |

 Present fully Integrated System, followed by Weakened System (assuming selected lines out) and Existing System (current system as is).

#### Assumptions

- Base case assumes all generation resources from LTCE plan and mapped to buses
- Include all transmission investment projects: new and upgrades
- System loads and generation are balanced: large thermal, small peaker, PV and storage, DG, CHP
- Capacitor banks adjusted to provide necessary reactive power support

#### Methodology

- Monitor all 38 kV and above facilities, for thermal and voltage violations
- N-0, system intact
- N-1 contingencies (NERC P1)
- N-2 Right-of-Way contingencies (NERC P7): Selected double circuit lines
- 100% of Rate A and B for normal and emergency (contingency) violations
- Bus voltage at 38 kV and above, 0.95 1.05 per unit for system intact and 0.9 1.1 per unit following a contingency

#### **Generation Dispatch – S4S2B**

| Total Generation   |          | 3384.2 | 1602  |          | 3590.2 | 1178  |  |
| Load               |          | 2295   | 2377  |          | 2161   | 2247  |  |
| Losses             |          | 32     | 24    |          | 29     | 21    |  |
| Load + Losses      |          | 2327   | 2401  |          | 2190   | 2268  |  |
| Storage            | 1320     | 1058   | 797   | 1400     | 1400   | 1090  |  |
| Gen - Load         |          | 0      | 0     |          | 0      | 0     |  |
| Reserve            |          |        | 541   |          |        | 391   |  |

- Reserve is calculated to accommodate a continuous supply in case of the biggest single unit is tripped out of service.
- For example: In night cases, the biggest unit is the new 302 MW CC F Class, therefore, at least 302 MW is assured from other resources
- Storage is charging (load) during the day and discharging (generation) at night

#### **Thermal and BESS Resource Comparison**

|         | Large & Medium CCGTs and Peakers |                                |                               | Storage              |                   |                   |
|---------|----------------------------------|--------------------------------|-------------------------------|----------------------|-------------------|-------------------|
| CASE ID | F - Class<br>Palo Seco<br>2025   | F - Class<br>Costa Sur<br>2025 | San Juan<br>5&6<br>Conversion | Peakers<br>2025 (MW) | BESS 2025<br>(MW) | BESS 2028<br>(MW) |
| S1S2B   | -                                | Eco instead                    | $\checkmark$                  | 504                  | 1,280             | 1,280             |
| S3S2B   | -                                | $\checkmark$                   | $\checkmark$                  | 348                  | 1,400             | 1,920             |
| S4S2B   | $\checkmark$                     | $\checkmark$                   | $\checkmark$                  | 371                  | 1,320             | 1,400             |
| S5S1B   | _                                | 369 MW<br>(2025&2028)          | $\checkmark$                  | 371                  | 1,200             | 1,200             |
| ESM     | $\checkmark$                     | $\checkmark$                   | $\checkmark$                  | 421                  | 920               | 1,120             |

- S1S2B is similar to S4S2B as the only major difference is the absence of the large CC F Class in Palo Seco and F Class unit in Costa Sur replaced by EcoEléctrica, supplemented by additional peakers
- S3S2B and S5S1B are also similar to S4S2B or S1S2B where the F class in Palo Seco is not in the mix and complimented by thermal peakers and additional BESS resources

#### **Observations**

- The loss of a 38 kV line line resulted in a radial feed to a 20.33 MVA of load causing a slight overload on the other 38 kV line. This is a local issue not really related to the IRP.
- Recommend to upgrade the affected line to higher rating based on preliminary observation
- No other thermal violations above 38kV were reported for all 10 power flow cases
- Low voltage violations at 38kV were reported in Arecibo near Dos Bocas area due to the loss of one of the 115 kV lines. This is also local in nature.

#### Summary

- As a complement of the MiniGrid analysis which evaluate the system conditions under 8 separated MiniGrids, Weakened system analysis evaluates the conditions in which the system may be lesser in strength, but still integrated
- The certain critical lines assumed to be out of service for an extended period of time after a major event, mostly in east and south
- AES is disconnected as a result
- S4S2B and ESM Night Peak cases assessed for both 2025 and 2028
- No thermal or voltage violations were reported under this assessment.

#### Transmission Steady State Analysis – *Existing System*

#### Summary

- In addition to the fully Integrated System, Weakened System and MiniGrid System analysis, the Existing System representing the PREPA transmission network currently as is also assessed
- Assuming system unreinforced and no proposed transmission investment
- The purpose is to mainly identify any constraints and reinforcements required to relieve constraints as a result of two major resources: 302 MW each at Yabucoa and Mayaguez
- Benchmark (without the units) and Study (with the units) cases were assessed
- In Study case the new units were dispatched to full capacity, and the generation in the rest of PREPA system was adjusted to maintain the same level
- Adding a CCGT at Mayaguez did not result in any violations.
- The unit in Yabucoa would result in overloads under certain contingencies.
- This overload will not occur under the ranforced system for Resiliency. Also PREPA has plan in place in the area that could address this issue.
